THE SPACE OF EMBEDDED MINIMAL SURFACES OF FIXED GENUS IN A 3-MANIFOLD I; ESTIMATES OFF THE AXIS FOR DISKS

TOBIAS H. COLDING AND WILLIAM P. MINICOZZI II

0. Introduction

This paper is the first in a series where we attempt to give a complete description of the space of all embedded minimal surfaces of fixed genus in a fixed (but arbitrary) closed Riemannian 3-manifold. The key for understanding such surfaces is to understand the local structure in a ball and in particular the structure of an embedded minimal disk in a ball in $\mathbf{R}^3$ (with the flat metric). This study is undertaken here and completed in [CM6]; see also [CM8], [CM9] where we have surveyed our results about embedded minimal disks. These local results are then applied in [CM7] where we describe the general structure of fixed genus surfaces in 3-manifolds.

We show here that if such an embedded minimal disk in $\mathbf{R}^3$ starts off as an almost flat multi-valued graph, then it will remain so indefinitely.

Let $\mathcal{P}$ be the universal cover of the punctured plane $\mathbf{C}\setminus\{0\}$ with global (polar) coordinates (ρ,θ). An N-valued graph Σ over the annulus $D_{r_2}\setminus D_{r_1}$ (see fig. 1) is a (single-valued) graph over

$$\{(\rho,\theta)\in\mathcal{P}\,|\,r_1<\rho<r_2 \text{ and } |\theta|\leq \pi\, N\}\,. \tag{0.1}$$

The middle sheet Σ^M (an annulus with a slit as in [CM3]) is the portion over

$$\{(\rho,\theta)\in\mathcal{P}\,|\,r_1<\rho<r_2 \text{ and } 0\leq\theta\leq 2\,\pi\}\,. \tag{0.2}$$

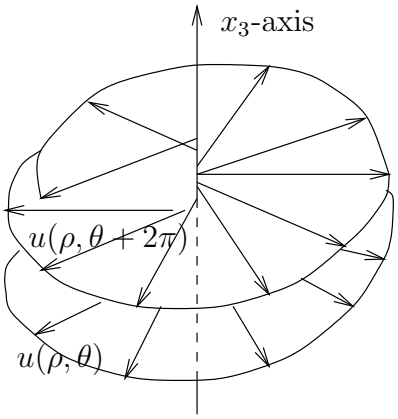

Figure 1. A multi-valued graph.

The first author was partially supported by NSF Grant DMS 9803253 and an Alfred P. Sloan Research Fellowship and the second author by NSF Grant DMS 9803144 and an Alfred P. Sloan Research Fellowship.

Theorem 0.3. See fig. 2. Given $\tau > 0$, there exist $N, \Omega, \epsilon > 0$ so: Let $\Omega\, r_0 < 1 < R_0/\Omega$, $\Sigma \subset B_{R_0} \subset \mathbf{R}^3$ be an embedded minimal disk, $\partial\Sigma \subset \partial B_{R_0}$. If Σ contains an N-valued graph Σ_g over $D_1 \setminus D_{r_0}$ with gradient $\leq \epsilon$ and $\Sigma_g \subset \{x_3^2 \leq \epsilon^2(x_1^2 + x_2^2)\}$, then Σ contains a 2-valued graph Σ_d over $D_{R_0/\Omega} \setminus D_{r_0}$ with gradient $\leq \tau$ and $(\Sigma_g)^M \subset \Sigma_d$.

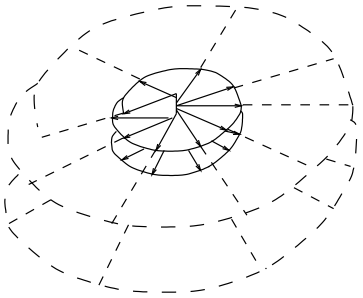

FIGURE 2. Theorem 0.3 - extending a small multi-valued graph in a disk.

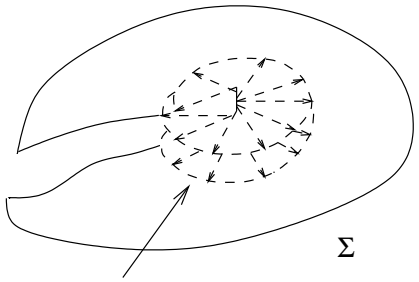

FIGURE 3. Theorem 0.4 - finding a small multi-valued graph in a disk near a point of large curvature.

Theorem 0.3 is particularly useful when combined with a result from [CM4] asserting that an embedded minimal disk with large curvature at a point contains a small almost flat multi-valued graph nearby. Namely:

Theorem 0.4. [CM4]. See fig. 3. Given $N, \omega > 1$, $\epsilon > 0$, there exists $C = C(N, \omega, \epsilon) > 0$ so: Let $0 \in \Sigma^2 \subset B_R \subset \mathbf{R}^3$ be an embedded minimal disk, $\partial\Sigma \subset \partial B_R$. If $\sup_{B_{r_0} \cap \Sigma} |A|^2 \leq 4\, C^2\, r_0^{-2}$ and $|A|^2(0) = C^2\, r_0^{-2}$ for some $0 < r_0 < R$, then there exist $\bar{R} < r_0/\omega$ and (after a rotation) an N-valued graph $\Sigma_g \subset \Sigma$ over $D_{\omega\bar{R}} \setminus D_{\bar{R}}$ with gradient $\leq \epsilon$, and $\text{dist}_\Sigma(0, \Sigma_g) \leq 4\, \bar{R}$.

Combining these two results with a standard blow up argument gives:

Theorem 0.5. [CM4]. Given $N \in \mathbf{Z}_+$, $\epsilon > 0$, there exist C_1, $C_2 > 0$ so: Let $0 \in \Sigma^2 \subset B_R \subset \mathbf{R}^3$ be an embedded minimal disk, $\partial\Sigma \subset \partial B_R$. If $\max_{B_{r_0} \cap \Sigma} |A|^2 \geq 4\, C_1^2\, r_0^{-2}$ for some $0 < r_0 < R$, then there exists (after a rotation) an N-valued graph $\Sigma_g \subset \Sigma$ over $D_{R/C_2} \setminus D_{2r_0}$ with gradient $\leq \epsilon$ and $\Sigma_g \subset \{x_3^2 \leq \epsilon^2\,(x_1^2 + x_2^2)\}$.

The multi-valued graphs given by Theorem 0.5 should be thought of (see [CM6]) as the basic building blocks of an embedded minimal disk. In fact, one should think of such a disk as being built out of such graphs by stacking them on top of each other. It will follow from Proposition II.2.12 that the separation between the sheets in such a graph grows sublinearly.

An important component of the proof of Theorem 0.3 is a version of it for stable minimal annuli with slits that start off as multi-valued graphs. Another component is a curvature estimate "between the sheets" for embedded minimal disks in $\mathbf{R}^3$; see fig. 4. We will think of an axis for such a disk Σ as a point or curve away from which the surface locally (in an extrinsic ball) has more than one component. With this weak notion of an axis, our estimate is that if one component of Σ is sandwiched between two others that connect to an axis, then the one that is sandwiched has curvature estimates; see Theorem I.0.8. The example to keep in mind is a helicoid and the components are "consecutive sheets" away from the axis.

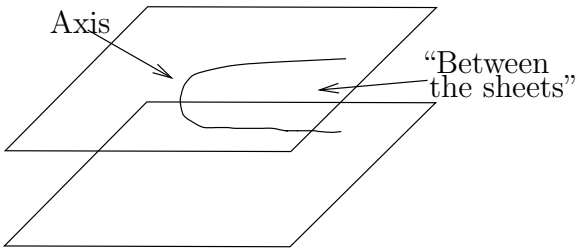

FIGURE 4. The estimate between the sheets: Theorem I.0.8.

Theorems 0.3, 0.4, 0.5 are local and are for simplicity stated and proven only in $\mathbf{R}^3$ although they can with only very minor changes easily be seen to hold for minimal disks in a sufficiently small ball in any given fixed Riemannian 3-manifold.

The paper is divided into 4 parts. In Part I, we show the curvature estimate "between the sheets" when the disk is in a thin slab. In Part II, we will show that certain stable disks with interior boundaries starting off as multi-valued graphs remain very flat (cf. Theorem 0.3). This result will be needed together with Part I in Part III to generalize the results of Part I to when the disk is not anymore assumed to lie in a slab. Part II will also be used together with Part III in Part IV to show Theorem 0.3.

Let x_1, x_2, x_3 be the standard coordinates on $\mathbf{R}^3$ and $\Pi : \mathbf{R}^3 \to \mathbf{R}^2$ orthogonal projection to $\{x_3 = 0\}$. For $y \in S \subset \Sigma \subset \mathbf{R}^3$ and $s > 0$, the extrinsic and intrinsic balls and tubes are

$$B_s(y) = \{x \in \mathbf{R}^3 \,|\, |x - y| < s\}\,, \quad T_s(S) = \{x \in \mathbf{R}^3 \,|\, \mathrm{dist}_{\mathbf{R}^3}(x, S) < s\}\,, \tag{0.6}$$

$$\mathcal{B}_s(y) = \{x \in \Sigma \,|\, \mathrm{dist}_\Sigma(x, y) < s\}\,, \mathcal{T}_s(S) = \{x \in \Sigma \,|\, \mathrm{dist}_\Sigma(x, S) < s\}\,. \tag{0.7}$$

D_s denotes the disk $B_s(0) \cap \{x_3 = 0\}$. K_Σ the sectional curvature of a smooth compact surface Σ and when Σ is immersed A_Σ will be its second fundamental form. When Σ is oriented, $\mathbf{n}_\Sigma$ is the unit normal. We will often consider the intersection of curves and surfaces with extrinsic balls. We assume that these intersect transversely since this can be achieved by an arbitrarily small perturbation of the radius.

Part I. Minimal disks in a slab

Let $\gamma_{p,q}$ denote the line segment from p to q and $\overline{p,q}$ the ray from p through q. A curve γ is *h-almost monotone* if given $y \in \gamma$, then $B_{4\,h}(y) \cap \gamma$ has only one component which intersects $B_{2\,h}(y)$. Our curvature estimate "between the sheets" is (see fig. 5):

Theorem I.0.8. There exist $c_1 \geq 4$, $2c_2 < c_4 < c_3 \leq 1$ so: Let $\Sigma^2 \subset B_{c_1\,r_0}$ be an embedded minimal disk with $\partial\Sigma \subset \partial B_{c_1\,r_0}$ and $y \in \partial B_{2\,r_0}$. Suppose $\Sigma_1, \Sigma_2, \Sigma_3$ are distinct components of $B_{r_0}(y) \cap \Sigma$ and $\gamma \subset (B_{r_0} \cup T_{c_2\,r_0}(\gamma_{0,y})) \cap \Sigma$ is a curve with $\partial\gamma = \{y_1, y_2\}$ where $y_i \in B_{c_2\,r_0}(y) \cap \Sigma_i$ and each component of $\gamma \setminus B_{r_0}$ is $c_2\,r_0$-almost monotone. Then any component Σ_3' of $B_{c_3\,r_0}(y) \cap \Sigma_3$ with y_1, y_2 in distinct components of $B_{c_4\,r_0}(y) \setminus \Sigma_3'$ is a graph.

The idea for the proof of Theorem I.0.8 is to show that if this were not the case, then we could find an embedded stable disk that would be almost flat and lie in the complement of the original disk. In fact, we can choose the stable disk to be sandwiched between the two components as well. The flatness would force the stable disk to eventually cross the axis in the original disk, contradicting that they were disjoint.

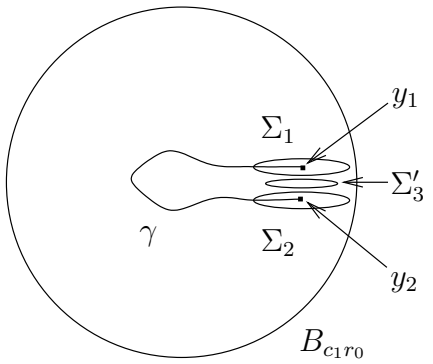

FIGURE 5. y_1, y_2, Σ_1, Σ_2, Σ_3', and γ in Theorem I.0.8.

In this part, we prove Theorem I.0.8 when the surface is in a slab, illustrating the key points (the full theorem, using the results of this part, will be proven later). Two simple facts about minimal surfaces in a slab will be used: (1) Stable surfaces in a slab must be graphical away from their boundary (see Lemma I.0.9 below) and (2) the maximum principle, and catenoid foliations in particular, force these surfaces to intersect a narrow cylinder about every vertical line (see the appendix).

Lemma I.0.9. Let $\Gamma \subset \{|x_3| \leq \beta\, h\}$ be a stable embedded minimal surface. There exist $C_g, \beta_s > 0$ so if $\beta \leq \beta_s$ and E is a component of $\mathbf{R}^2 \setminus T_h(\Pi(\partial\Gamma))$, then each component of $\Pi^{-1}(E) \cap \Gamma$ is a graph over E of a function u with $|\nabla_{\mathbf{R}^2} u| \leq C_g\, \beta$.

Proof. If $\mathcal{B}_h(y) \subset \Gamma$, [Sc] gives that $|A|^2 \leq C_s\, h^{-2}$ on $\mathcal{B}_{h/2}(y)$. Since $\Delta_\Gamma x_3 = 0$, [ChY] yields

$$\sup_{\mathcal{B}_{h/4}(y)} |\nabla_\Gamma x_3| \leq \bar{C}_g\, h^{-1} \sup_{\mathcal{B}_{h/2}(y)} |x_3| \leq \bar{C}_g\, \beta\,, \tag{I.0.10}$$

where $\bar{C}_g = \bar{C}_g(C_s)$. Since $|\nabla_{\mathbf{R}^2} u|^2 = |\nabla_\Gamma x_3|^2 \,/\, (1 - |\nabla_\Gamma x_3|^2)$, this gives the lemma. □

The next lemma shows that if an embedded minimal disk Σ in the intersection of a ball with a thin slab is not graphical near the center, then it contains a curve γ coming close to the center and connecting two boundary points which are close in $\mathbf{R}^3$ but not in Σ. The constant β_A is defined in (A.6).

Lemma I.0.11. Let $\Sigma^2 \subset B_{60\,h} \cap \{|x_3| \leq \beta_A\, h\}$ be an embedded minimal disk with $\partial\Sigma \subset \partial B_{60\,h}$ and let $z_b \in \partial B_{50\,h}$. If a component Σ' of $B_{5\,h} \cap \Sigma$ is not a graph, then there are distinct components S_1, S_2 of $B_{8\,h}(z_b) \cap \Sigma$, $z_i \in B_{h/4}(z_b) \cap S_i$ and a curve $\gamma \subset (B_{30\,h} \cup T_h(\gamma_{q,z_b})) \cap \Sigma$ with $\partial\gamma = \{z_1, z_2\}$ and $\gamma \cap \Sigma' \neq \emptyset$. Here $q \in B_{50\,h}(z_b) \cap \partial B_{30\,h}$.

Proof. See fig. 6. Since Σ' is not graphical, we can find $z \in \Sigma'$ with Σ vertical at z (i.e., $|\nabla_\Sigma x_3|(z) = 1$). Fix $y \in \partial B_{4\,h}(z)$ so $\gamma_{y,z}$ is normal to Σ at z. Then $f_y(z) = 4\,h$ (see (A.5)). Let y' be given by that $y' \in \partial B_{10\,h}(y)$ and $z \in \gamma_{y,y'}$. The first step is to use the catenoid foliation f_y to build the desired curve on the scale of h; see fig. 7. The second and third steps will bring the endpoints of this curve out near z_b.

Any simple closed curve $\sigma \subset \Sigma \setminus \{f_y > 4\,h\}$ bounds a disk $\Sigma_\sigma \subset \Sigma$. By Lemma A.8, f_y has no maxima on $\Sigma_\sigma \cap \{f_y > 4\,h\}$ so $\Sigma_\sigma \cap \{f_y > 4\,h\} = \emptyset$. On the other hand, by Lemma A.7, we get a neighborhood $U_z \subset \Sigma$ of z where $U_z \cap \{f_y = 4\,h\} \setminus \{z\}$ is the union of

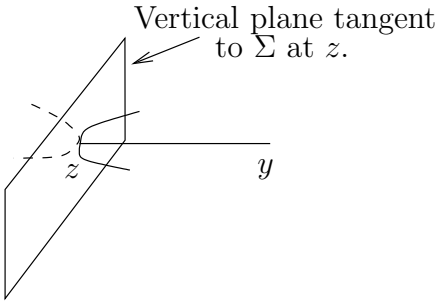

FIGURE 6. Proof of Lemma I.0.11: Vertical plane tangent to Σ at z. Since Σ is minimal, we get locally near z on one side of the plane two different components. Next place a catenoid foliation centered at y and tangent to Σ at z.

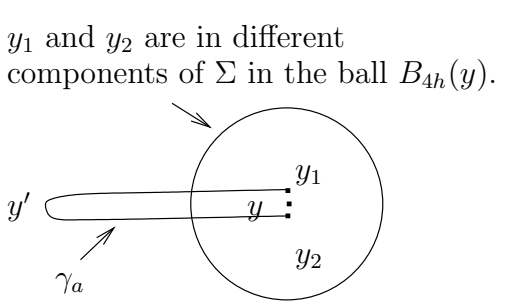

FIGURE 7. Proof of Lemma I.0.11: Step 1: Using the catenoid foliation, we build out the curve to scale h.

$2n \geq 4$ disjoint embedded arcs meeting at z. Moreover, $U_z \setminus \{f_y \geq 4\,h\}$ has n components $U_1, \ldots, U_n$ and $\overline{U_i} \cap \overline{U_j} = \{z\}$ for $i \neq j$. If a simple curve $\tilde{\sigma}_z \subset \Sigma \setminus \{f_y \geq 4\,h\}$ connects U_1 to U_2, connecting $\partial\tilde{\sigma}_z$ by a curve in U_z gives a simple closed curve $\sigma_z \subset \Sigma \setminus \{f_y > 4\,h\}$ with $\tilde{\sigma}_z \subset \sigma_z$ and $\sigma_z \cap \{f_y \geq 4\,h\} = \{z\}$. Hence, σ_z bounds a disk $\Sigma_{\sigma_z} \subset \Sigma \setminus \{f_y > 4\,h\}$. By construction, $U_z \cap \Sigma_{\sigma_z} \setminus \cup_i \overline{U_i} \neq \emptyset$, which is a contradiction. This shows that U_1, U_2 are contained in components $\Sigma^1_{4\,h} \neq \Sigma^2_{4\,h}$ of $\Sigma \setminus \{f_y \geq 4\,h\}$ with $z \in \overline{\Sigma^1_{4\,h}} \cap \overline{\Sigma^2_{4\,h}}$. For $i = 1, 2$, Lemma A.8 and (A.6) give $y^a_i \in B_{h/4}(y) \cap \Sigma^i_{4\,h}$. Corollary A.10 gives $\nu_i \subset T_h(\gamma_{y,y'}) \cap \Sigma$ with $\partial\nu_i = \{y^a_i, y^b_i\}$ where $y^b_i \in B_{h/4}(y')$. There are now two cases: If y^b_1 and y^b_2 do not connect in $B_{4\,h}(y') \cap \Sigma$, then take $\gamma_0 \subset B_{5\,h}(y) \cap \Sigma$ from y^a_1 to y^a_2 and set $\gamma_a = \nu_1 \cup \gamma_0 \cup \nu_2$ and $y_i = y^b_i$. Otherwise, if $\hat{\gamma}_0 \subset B_{4\,h}(y') \cap \Sigma$ connects y^b_1 and y^b_2, set $\gamma_a = \nu_1 \cup \hat{\gamma}_0 \cup \nu_2$ and $y_i = y^a_i$. After possibly switching y and y', we get a curve $\gamma_a \subset (T_h(\gamma_{y,y'}) \cup B_{5\,h}(y')) \cap \Sigma$ with $\partial\gamma_a = \{y_1, y_2\} \subset B_{h/4}(y)$ and $y_i \in S^a_i$ for components $S^a_1 \neq S^a_2$ of $B_{4\,h}(y) \cap \Sigma$. This completes the first step.

Second, we use the maximum principle to restrict the possible curves from y_1 to y_2; see fig. 8. Set

$$H = \{x \,|\, \langle y - y', x - y\rangle > 0\}\,. \tag{I.0.12}$$

If $\eta_{1,2} \subset T_h(H) \cap \Sigma$ connects y_1 and y_2, then $\eta_{1,2} \cup \gamma_a$ bounds a disk $\Sigma_{1,2} \subset \Sigma$. Since $\eta_{1,2} \subset T_h(H)$, $\partial B_{8\,h}(y') \cap \partial\Sigma_{1,2}$ consists of an odd number of points in each S^a_i and hence $\partial B_{8\,h}(y') \cap \Sigma_{1,2}$ contains a curve from S^a_1 to S^a_2. However, S^a_1 and S^a_2 are distinct components of $B_{4\,h}(y) \cap \Sigma$, so this curve contains

$$y_{1,2} \in \partial B_{4\,h}(y) \cap \partial B_{8\,h}(y') \cap \Sigma_{1,2}\,. \tag{I.0.13}$$

By construction, $\Pi(y_{1,2})$ is in an unbounded component of $\mathbf{R}^2 \setminus T_{h/4}(\Pi(\partial\Sigma_{1,2}))$, contradicting Corollary A.11. Hence, y_1 and y_2 cannot be connected in $T_h(H) \cap \Sigma$.

Third, we extend γ_a. There are two cases: (A) If $z_b \in H$, Corollary A.10 gives

$$\tilde{\nu}_1, \tilde{\nu}_2 \subset T_h(\gamma_{y,z_b}) \cap \Sigma \subset T_h(H) \cap \Sigma \tag{I.0.14}$$

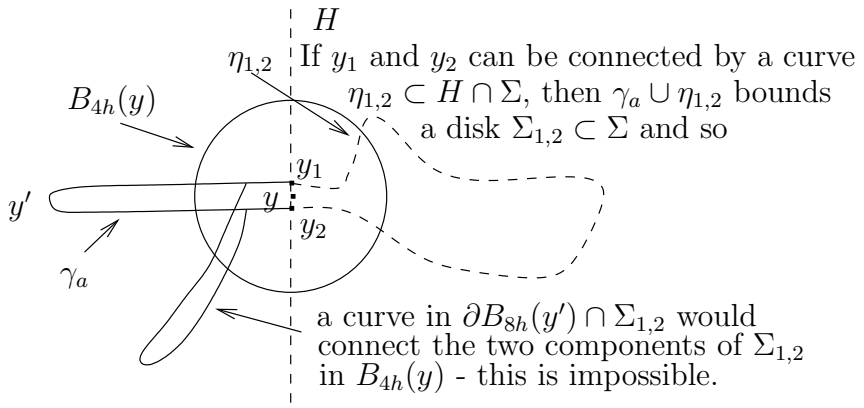

FIGURE 8. Proof of Lemma I.0.11: Step 2: y_1 and y_2 cannot connect in the half-space H since this would give a point in $\Sigma_{1,2}$ far from $\partial\Sigma_{1,2}$, contradicting Corollary A.10.

from y_1, y_2 to $z_1, z_2 \in B_{h/4}(z_b)$, respectively. (B) If $z_b \notin H$, then fix $z_c \in \partial B_{20\,h}(y) \cap \Pi(\partial H)$ on the same side of $\Pi(\overline{y, y'})$ as $\Pi(z_b)$ and fix $z_d \in \partial B_{10\,h}(z_c) \setminus H$ with γ_{z_c,z_d} orthogonal to ∂H (so $\Pi(y'), \Pi(y), z_c, z_d$ form a $10\,h$ by $20\,h$ rectangle). Corollary A.10 gives

$$\tilde{\nu}_1, \tilde{\nu}_2 \subset T_h(\gamma_{y,z_c} \cup \gamma_{z_c,z_d} \cup \gamma_{z_d,z_b}) \cap \Sigma \tag{I.0.15}$$

from y_1, y_2 to $z_1, z_2 \in B_{h/4}(z_b)$, respectively. In either case, set $\gamma = \tilde{\nu}_1 \cup \gamma_a \cup \tilde{\nu}_2$. Set $q = \partial B_{30\,h}(y) \cap \gamma_{y,z_b}$ (in (A)) or $q = \partial B_{30\,h}(y) \cap \gamma_{z_c,z_b}$ (in (B)). Applying Corollary A.11 as above, z_1, z_2 are in distinct components of $B_{8\,h}(z_b) \cap \Sigma$. □

The next result illustrates the main ideas for Theorem I.0.8 in the simpler case where Σ is in a slab. Set $\beta_3 = \min\{\beta_A, \beta_s, \tan\theta_0/(2\,C_g)\}$; C_g, β_s are defined in Lemma I.0.9, θ_0 in (A.3), and β_A in (A.6).

Proposition I.0.16. Let $\Sigma \subset B_{4\,r_0} \cap \{|x_3| \leq \beta_3\, h\}$ be an embedded minimal disk with $\partial\Sigma \subset \partial B_{4\,r_0}$ and let $y \in \partial B_{2\,r_0}$. Suppose that $\Sigma_1, \Sigma_2, \Sigma_3$ are distinct components of $B_{r_0}(y) \cap \Sigma$ and $\gamma \subset (B_{r_0} \cup T_h(\gamma_{0,y})) \cap \Sigma$ is a curve with $\partial\gamma = \{y_1, y_2\}$ where $y_i \in B_h(y) \cap \Sigma_i$ and each component of $\gamma \setminus B_{r_0}$ is h-almost monotone. Then any component Σ_3' of $B_{r_0-80\,h}(y) \cap \Sigma_3$ for which y_1, y_2 are in distinct components of $B_{5\,h}(y) \setminus \Sigma_3'$ is a graph.

Proof. We will suppose that Σ_3' is not a graph and deduce a contradiction. Fix a vertical point $z \in \Sigma_3'$. Define z_0, y_0, y_b on the ray $\overline{0, y}$ by $z_0 = \partial B_{3\,r_0-21\,h} \cap \overline{0, y}$, $y_0 = \partial B_{3\,r_0-10\,h} \cap \overline{0, y}$, and $y_b = \partial B_{4\,r_0} \cap \overline{0, y}$. Set $z_b = \partial B_{50\,h}(z) \cap \gamma_{z,z_0}$. Define the half-space

$$H = \{x \,|\, \langle x - z_0, z_0\rangle > 0\}\,. \tag{I.0.17}$$

The first step is to find a simple curve $\gamma_3 \subset (B_{r_0-20\,h}(y) \cup T_h(\gamma_{y,y_b})) \cap \Sigma$ which can be connected to Σ_3' in $B_{r_0-20\,h}(y) \cap \Sigma$, with $\partial\gamma_3 \subset \partial\Sigma$, and so $\partial B_{r_0-10\,h}(y) \cap \gamma_3$ consists of an odd number of points in each of two distinct components of $H \cap \Sigma$. To do that, we begin by applying Lemma I.0.11 to get $q \in B_{50\,h}(z_b) \cap \partial B_{30\,h}(z)$, distinct components S_1, S_2 of

$B_{8\,h}(z_b) \cap \Sigma$ with $z_i \in B_{h/4}(z_b) \cap S_i$, and a curve

$$\gamma_3^\star \subset (B_{30\,h}(z) \cup T_h(\gamma_{q,z_b})) \cap \Sigma,\ \partial\gamma_3^\star = \{z_1, z_2\}\,,\ \gamma_3^\star \cap \Sigma_3' \neq \emptyset\,. \tag{I.0.18}$$

Corollary A.10 gives h-almost monotone curves $\nu_1, \nu_2 \subset T_h(\gamma_{z_b,z_0} \cup \gamma_{z_0,y_b}) \cap \Sigma$ from z_1, z_2, respectively, to $\partial\Sigma$. Then $\gamma_3 = \nu_1 \cup \gamma_3^\star \cup \nu_2$ extends $\gamma_3^\star$ to $\partial\Sigma$. Fix $z^+ \in B_h(y_0) \cap \nu_1$ and $z^- \in B_h(y_0) \cap \nu_2$. We will show that z^+, z^- do not connect in $H \cap \Sigma$. If $\eta_+^- \subset H \cap \Sigma$ connects z^+ and z^-, then η_+^- together with the portion of γ_3 from z^+ to z^- bounds a disk $\Sigma_+^- \subset \Sigma$. Using the almost monotonicity of each ν_i, $\partial B_{50\,h}(z) \cap \partial\Sigma_+^-$ consists of an odd number of points in each S_i. Consequently, a curve $\sigma_+^- \subset \partial B_{50\,h}(z) \cap \Sigma_+^-$ connects S_1 to S_2 and so $\sigma_+^- \setminus B_{8\,h}(z_b) \neq \emptyset$. This would contradict Corollary A.11 and we conclude that there are distinct components Σ_H^+ and Σ_H^- of $H \cap \Sigma$ with $z^\pm \in \Sigma_H^\pm$. Finally, removing any loops in γ_3 (so it is simple) gives the desired curve.

The second step is to find disjoint stable disks $\Gamma_1, \Gamma_2 \subset B_{r_0-2\,h}(y) \setminus \Sigma$ with $\partial\Gamma_i \subset \partial B_{r_0-2\,h}(y)$ and graphical components Γ_i' of $B_{r_0-4\,h}(y) \cap \Gamma_i$ so Σ_3' is between Γ_1', Γ_2' and y_1, y_2, Σ_3' are each in their own component of $B_{r_0-4\,h}(y) \setminus (\Gamma_1' \cup \Gamma_2')$. To achieve this, we will solve two Plateau problems using Σ as a barrier and then use that Σ_3' separates y_1, y_2 near y to get that these are in different components. Let Σ_1', Σ_2' be the components of $B_{r_0-2\,h}(y) \cap \Sigma$ with $y_1 \in \Sigma_1', y_2 \in \Sigma_2'$. By the maximum principle, each of these is a disk. Let Σ_{y_2} be the component of $B_{3\,h}(y_1) \cap \Sigma$ with $y_2 \in \Sigma_{y_2}$. Since $y_1 \notin \Sigma_{y_2}$, Lemma A.8 gives $y_2' \in \Sigma_{y_2} \setminus N_{\theta_0}(y_1)$ with $\theta_0 > 0$ from (A.3). Hence, the vector $y_1 - y_2'$ is nearly orthogonal to the slab, i.e.,

$$|\Pi(y_2' - y_1)| \leq |y_2' - y_1| \cos\theta_0\,. \tag{I.0.19}$$

Since Σ_3' separates y_1, y_2 in $B_{5\,h}(y)$, we get $y_3 \in \gamma_{y_1,y_2'} \cap \Sigma_3'$. Fix a component Ω_1 of $B_{r_0-2\,h}(y) \setminus \Sigma$ containing a component of $\gamma_{y_1,y_3} \setminus \Sigma$ with exactly one endpoint in Σ_1'. By [MeYa], we get a stable embedded disk $\Gamma_1 \subset \Omega_1$ with $\partial\Gamma_1 = \partial\Sigma_1'$. Similarly, let Ω_2 be a component of $B_{r_0-2\,h}(y) \setminus (\Sigma \cup \Gamma_1)$ containing a component of $\gamma_{y_3,y_2'} \setminus (\Sigma \cup \Gamma_1)$ with exactly one endpoint in Σ_2'. Again by [MeYa], we get a stable embedded disk $\Gamma_2 \subset \Omega_2$ with $\partial\Gamma_2 = \partial\Sigma_2'$. Since $\partial\Gamma_1, \partial\Gamma_2$ are linked in Ω_1, Ω_2 with (segments of) $\gamma_{y_1,y_3}, \gamma_{y_3,y_2'}$, respectively, we get components Γ_i' of $B_{r_0-4h}(y) \cap \Gamma_i$ with $z_1^\Gamma \in \Gamma_1' \cap \gamma_{y_1,y_3}$ and $z_2^\Gamma \in \Gamma_2' \cap \gamma_{y_3,y_2'}$. By Lemma I.0.9, each Γ_i' is a graph of a function u_i with $|\nabla u_i| \leq C_g\,\beta_3$. Hence, since $1 + C_g^2\,\beta_3^2 < 1/\cos^2\theta_0$,

$$\Gamma_i' \setminus \{z_i^\Gamma\} \subset N_{\theta_0}(z_i^\Gamma)\,. \tag{I.0.20}$$

By (I.0.19), $\gamma_{y_1,y_2'} \cap N_{\theta_0}(z_i^\Gamma) = \emptyset$, so (I.0.20) implies that $\Gamma_i' \cap \gamma_{y_1,y_2'} = \{z_i^\Gamma\}$. In particular, y_1, y_2, y_3 are in distinct components of $B_{r_0-4\,h} \setminus (\Gamma_1' \cup \Gamma_2')$. This completes the second step.

Set $\hat{y} = \partial B_{r_0+10\,h} \cap \gamma_{0,y}$. Let $\hat{\gamma}$ be the component of $B_{r_0+10\,h} \cap \gamma$ with $B_{r_0} \cap \hat{\gamma} \neq \emptyset$. Then $\partial\hat{\gamma} = \{\hat{y}_1, \hat{y}_2\}$ with $\hat{y}_i \in B_h(\hat{y}) \cap \Sigma_i'$.

The third step is to solve the Plateau problem with γ_3 together with part of $\partial\Sigma \subset \partial B_{4\,r_0}$ as the boundary to get a stable disk $\Gamma_3 \subset B_{4r_0} \setminus \Sigma$ passing between $\hat{y}_1, \hat{y}_2$. To do this, note that the curve γ_3 divides the disk Σ into two sub-disks Σ_3^+, Σ_3^-. Let Ω^+, Ω^- be the components of $B_{4\,r_0} \setminus (\Sigma \cup \Gamma_1 \cup \Gamma_2)$ with $\gamma_3 \subset \partial\Omega^+ \cap \partial\Omega^-$. Note that Ω^+, Ω^- are mean convex in the sense of [MeYa] since $\partial\Gamma_1 \cup \partial\Gamma_2 \subset \Sigma$ and $\partial\Sigma \subset \partial B_{4\,r_0}$. Using the first step, we can label Ω^+, Ω^- so z^+, z^- do not connect in $H \cap \Omega^+$. By [MeYa], we get a stable embedded disk $\Gamma_3 \subset \Omega^+$ with $\partial\Gamma_3 = \partial\Sigma_3^+$. Using the almost monotonicity, $\partial B_{r_0-10\,h}(y) \cap \partial\Gamma_3$ consists of an odd number of points in each of Σ_H^+, Σ_H^-. Hence, there is a curve $\gamma_+^- \subset \partial B_{r_0-10\,h}(y) \cap \Gamma_3$ from Σ_H^+ to Σ_H^-.

By construction, $\gamma_+^- \setminus B_{8\,h}(y_0) \neq \emptyset$. Hence, since $\partial B_{r_0-10\,h}(y) \cap T_h(\partial\Gamma_3) \subset B_{3\,h}(y_0)$, Lemma I.0.9 gives $\hat{z} \in B_h(\hat{y}_1) \cap \gamma_+^-$. By the second step, Γ_3 is between Γ_1' and Γ_2'.

Let $\hat{\Gamma}_3$ be the component of $B_{r_0+19\,h} \cap \Gamma_3$ with $\hat{z} \in \hat{\Gamma}_3$. By Lemma I.0.9, $\hat{\Gamma}_3$ is a graph. Finally, since $\hat{\gamma} \subset B_{r_0+10\,h}$ and $\hat{\Gamma}_3$ passes between $\partial\hat{\gamma}$, this forces $\hat{\Gamma}_3$ to intersect $\hat{\gamma}$. This contradiction completes the proof. □

Part II. Estimates for stable annuli with slits

In this part, we will show that certain stable disks starting off as multi-valued graphs remain the same (see Theorem II.0.21 below). This is needed in Part III when we generalize the results of Part I to when the surface is not anymore in a slab and in Part IV when we show Theorem 0.3.

Theorem II.0.21. Given $\tau > 0$, there exist $N_1, \Omega_1, \epsilon > 0$ so: Let $\Omega_1\, r_0 < 1 < R_0/\Omega_1$, $\Sigma \subset B_{R_0}$ be a stable embedded minimal disk, $\partial\Sigma \subset B_{r_0} \cup \partial B_{R_0} \cup \{x_1 = 0\}$, $\partial\Sigma \setminus \partial B_{R_0}$ is connected. If Σ contains an N_1-valued graph Σ_g over $D_1 \setminus D_{r_0}$ with gradient $\leq \epsilon$, $\Pi^{-1}(D_{r_0}) \cap \Sigma^M \subset \{|x_3| \leq \epsilon\, r_0\}$, and a curve $\eta \subset \Pi^{-1}(D_{r_0}) \cap \Sigma \setminus \partial B_{R_0}$ connects Σ_g to $\partial\Sigma \setminus \partial B_{R_0}$, then Σ contains a 2-valued graph Σ_d over $D_{R_0/\Omega_1} \setminus D_{r_0}$ with gradient $\leq \tau$.

Two analytical results go into the proof of this extension theorem. First, we show that if an almost flat multi-valued graph sits inside a stable disk, then the outward defined intrinsic sector from a curve which is a multi-valued graph over a circle has a subsector which is almost flat (see Corollary II.1.23 below). As the initial multi-valued graph becomes flatter and the number of sheets in it go up, the subsector becomes flatter. The second analytical result that we will need is that in a multi-valued minimal graph the distance between the sheets grows sublinearly (Proposition II.2.12).

After establishing these two facts, the first application (Corollary II.3.1) is to extending the middle sheet as a multi-valued graph. This is done by dividing the initial multi-valued graph (or curve in the graph that is itself a multi-valued graph over the circle) into three parts where the middle sheet is the second part. The idea is then that the first and third parts have subsectors which are almost flat multi-valued graphs and the middle part (which has curvature estimates since it is stable) is sandwiched between the two others. Hence its sector is also almost flat.

A thing that adds some technical complications to the above picture is that in the analytical result about almost flat subsectors it is important that the ratio between the size of the initial multi-valued graph and how far one can go out is fixed. This is because the estimate for the subsector comes from a total curvature estimate which is in terms of this ratio (see (II.1.2)) and can only be made small by looking at a fixed large number of rotations for the graph. This forces us to successively extend the multi-valued graph. The issue is then to make sure that as we move out in the sector and repeat the argument we have essentially not lost sheets. This is taken care of by using the sublinear growth of the separation between the sheets together with the Harnack inequality (Lemma II.3.8) and the maximum principle (Corollary II.3.1). (The maximum principle is used to make sure that as we try to recover sheets after we have moved out then we don't hit the boundary of the disk before we have recovered essentially all of the sheets that we started with.) The last thing is a result from [CM3] to guarantee that as we patch together these multi-valued graphs coming from different scales then the surface that we get is still a multi-valued graph over a fixed plane.

Unless otherwise stated in this part, Σ will be a stable embedded disk. Let $\gamma \subset \Sigma$ be a simple curve with unit normal $\mathbf{n}_\gamma$ and geodesic curvature k_g (with respect to $\mathbf{n}_\gamma$). We will always assume that γ' does not vanish. Given $R_1 > 0$, we define the intrinsic sector, see fig. 9,

$$S_{R_1}(\gamma) = \cup_{x\in\gamma}\gamma_x\,, \tag{II.0.22}$$

where γ_x is the (intrinsic) geodesic starting at $x \in \gamma$, of length R_1, and initial direction $\mathbf{n}_\gamma(x)$. For $0 < r_1 < R_1$, set $S_{r_1,R_1}(\gamma) = S_{R_1}(\gamma) \setminus S_{r_1}(\gamma)$ and $\rho(x) = \mathrm{dist}_{S_{R_1}(\gamma)}(x,\gamma)$. For example, if $\gamma = \partial D_{r_1} \subset \mathbf{R}^2$ and $\mathbf{n}_\gamma(x) = x/|x|$, then S_{r_2,R_1} is the annulus $D_{R_1+r_1} \setminus D_{r_2+r_1}$.

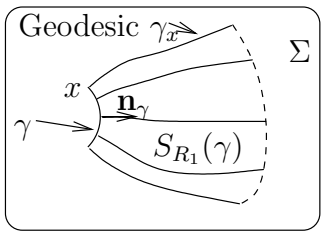

FIGURE 9. An intrinsic sector over a curve γ defined in (II.0.22).

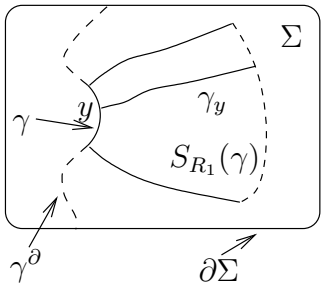

FIGURE 10. The curve γ^∂ containing γ goes to $\partial\Sigma$. ($\gamma^\partial \setminus \gamma$ is dotted.)

Note that if $k_g > 0$, $S_{R_1}(\gamma) \cap \partial\Sigma = \emptyset$, and there is a simple curve $\gamma^\partial \subset \Sigma$ with $\gamma \subset \gamma^\partial$, $\partial\gamma^\partial \subset \partial\Sigma$, and $\gamma_x \cap \gamma^\partial = \{x\}$ for any γ_x as above (see fig. 10), then the normal exponential map from γ (in direction $\mathbf{n}_\gamma$) gives a diffeomorphism to $S_{R_1}(\gamma)$. Namely, by the Gauss-Bonnet theorem, an n-gon in Σ with concave sides and n interior angles $\alpha_i > 0$ has

$$(n-2)\,\pi \geq \sum_{i=1}^{n} \alpha_i - \int k_g \geq \sum_{i=1}^{n} \alpha_i\,. \tag{II.0.23}$$

In particular, $n > 2$ always and if $\sum_i \alpha_i > \pi$, then $n > 3$. Fix $x, y \in \gamma$ and geodesics γ_x, γ_y as above. If γ_x had a self-intersection, then it would contain a simple geodesic loop, contradicting (II.0.23). Similarly, if γ_x were to intersect γ_y, then we would get a concave triangle with $\alpha_1 = \alpha_2 = \pi/2$ (since γ_x, γ_y don't cross γ^∂), contradicting (II.0.23).

Note also that $S_{r_1,R_1}(\gamma) = S_{R_1-r_1}(S_{r_1,r_1}(\gamma))$ for $0 < r_1 < R_1$.

II.1. Almost flat subsectors

We will next show that certain stable sectors contain almost flat subsectors.

Lemma II.1.1. Let $\gamma \subset \Sigma$ be a curve with $\mathrm{Length}(\gamma) \leq 3\,\pi\,m\,r_1$, $0 < k_g < 2/r_1$, $\mathrm{dist}_\Sigma(S_{R_1}(\gamma), \partial\Sigma) \geq r_1/2$, $R_1 > 2\,r_1$. If there is a simple curve $\gamma^\partial \subset \Sigma$ with $\gamma \subset \gamma^\partial$, $\partial\gamma^\partial \subset \partial\Sigma$, and $\gamma_x \cap \gamma^\partial = \{x\}$ for $x \in \gamma$, then for $\Omega > 2$ and $2\,r_1 \leq t \leq 3R_1/4$

$$\int_{S_{\Omega r_1, R_1/\Omega}(\gamma)} |A|^2 \leq C_1\,R_1/r_1 + C_2\,m/\log\Omega\,, \tag{II.1.2}$$

$$t\int_\gamma k_g \leq \mathrm{Length}(\{\rho = t\}) \leq C_3\,(m + R_1/r_1)\,t\,. \tag{II.1.3}$$

Proof. The boundary of $S_{R_1} = S_{R_1}(\gamma)$ has four pieces: γ, $\{\rho = R_1\}$, and the sides γ_a, γ_b. Set

$$\ell(t) = \text{Length}\left(\{\rho = t\}\right), \tag{II.1.4}$$

$$K(t) = \int_{S_t} |A|^2 . \tag{II.1.5}$$

Since the exponential map is an embedding, an easy calculation gives

$$\ell'(t) = \int_{\{\rho=t\}} k_g > 0 . \tag{II.1.6}$$

Let $d\mu$ be 1-dimensional Hausdorff measure on the level sets of ρ. The Jacobi equation gives

$$\frac{d}{dt}(k_g \, d\mu) = |A|^2/2 \, d\mu . \tag{II.1.7}$$

Set $\bar{K}(t) = \int_0^t K(s)\, ds$. Integrating (II.1.7) twice, (II.1.6) yields

$$\ell(t) = \ell(0) + \int_0^t \left(\int_\gamma k_g + K(s)/2 \right) ds = \text{Length}(\gamma) + t \int_\gamma k_g + \bar{K}(t)/2 . \tag{II.1.8}$$

This gives the first inequality in (II.1.3). Again by the coarea formula, (II.1.8) gives

$$\begin{aligned} R_1^{-2} \, \text{Area}(S_{R_1}) = R_1^{-2} \int_0^{R_1} \ell(t) &\leq R_1^{-1} \, \text{Length}(\gamma) + \int_\gamma k_g/2 + R_1^{-2} \int_0^{R_1} \bar{K}(t)/2 \\ &\leq 6\,\pi\, m + R_1^{-2} \int_0^{R_1} \bar{K}(t)/2 , \end{aligned} \tag{II.1.9}$$

where the last inequality used $k_g < 2/r_1$ on γ, $\text{Length}(\gamma) \leq 3\,\pi\, m\, r_1$, and $R_1 > 2\, r_1$.

Define a function ψ on S_{R_1} by $\psi = \psi(\rho) = 1 - \rho/R_1$ and set $d_S = \text{dist}_\Sigma(\cdot, \gamma_a \cup \gamma_b)$. Define functions χ_1, χ_2 on S_{R_1} by

$$\chi_1 = \chi_1(d_S) = \begin{cases} d_S/r_1 & \text{if } 0 \leq d_S \leq r_1 , \\ 1 & \text{otherwise} , \end{cases} \tag{II.1.10}$$

$$\chi_2 = \chi_2(\rho) = \begin{cases} \rho/r_1 & \text{if } 0 \leq \rho \leq r_1 , \\ 1 & \text{otherwise} . \end{cases} \tag{II.1.11}$$

Set $\chi = \chi_1\, \chi_2$. Using $|A|^2 \leq C\, r_1^{-2}$ (by [Sc]) and standard comparison theorems to bound the area of a tubular neighborhood of the boundary, we get

$$\text{Area}(S_{R_1} \cap \{\chi < 1\}) \leq \tilde{C}\, (R_1\, r_1 + m\, r_1^2) , \tag{II.1.12}$$

$$E(\chi_1) + \int_{S_{R_1} \cap \{\chi_1 < 1\}} |A|^2 \leq \tilde{C}\, R_1/r_1 , \tag{II.1.13}$$

$$E(\chi) + \int_{S_{R_1} \cap \{\chi < 1\}} |A|^2 \leq \tilde{C}\, (R_1/r_1 + m) . \tag{II.1.14}$$

Substituting $\chi\psi$ into the stability inequality, the Cauchy-Schwarz inequality and (II.1.14) give

$$\int |A|^2\chi^2\psi^2 \leq \int |\nabla(\chi\psi)|^2 = \int \left(\chi^2|\nabla\psi|^2 + 2\chi\,\psi\langle\nabla\chi,\nabla\psi\rangle + \psi^2|\nabla\chi|^2\right)$$
$$\leq 2\int \chi^2|\nabla\psi|^2 + 2\,\tilde{C}(R_1/r_1 + m)\,. \tag{II.1.15}$$

Using (II.1.14) and the coarea formula, we have

$$\int_0^{R_1} \psi^2(t)\,K'(t) = \int_{S_{R_1}} |A|^2\psi^2 \leq \int |A|^2\chi^2\psi^2 + \tilde{C}\,(R_1/r_1 + m)\,. \tag{II.1.16}$$

Integrating by parts twice in (II.1.16), (II.1.15) gives

$$2\,R_1^{-2}\int_0^{R_1} \bar{K}(t) = \int_0^{R_1} \bar{K}(t)(\psi^2)'' = -\int_0^{R_1} K(t)(\psi^2)' \tag{II.1.17}$$
$$= \int_0^{R_1} \psi^2 K'(t) \leq 3\,\tilde{C}\,(R_1/r_1 + m) + 2R_1^{-2}\int_0^{R_1} \ell(t)\,.$$

Note that all integrals in (II.1.17) are in one variable and there is a slight abuse of notation in regarding ψ as a function on both $[0, R_1]$ and S_{R_1}. Substituting (II.1.9), (II.1.17) gives

$$4\,R_1^{-2}\int_0^{R_1} \ell(t) \leq 24\,\pi\,m + 3\,\tilde{C}\,(R_1/r_1 + m) + 2\,R_1^{-2}\int_0^{R_1} \ell(t)\,. \tag{II.1.18}$$

In particular, (II.1.18) gives

$$R_1^{-2}\mathrm{Area}(S_{R_1}) \leq C_4\,(R_1/r_1 + m)\,. \tag{II.1.19}$$

Since $\ell(t)$ is monotone increasing (by (II.1.6)), (II.1.19) gives the second inequality in (II.1.3) for $t = 3\,R_1/4$. Since the above argument applies with R_1 replaced by t where $2\,r_1 < t < R_1$, we get (II.1.3) for $2\,r_1 \leq t \leq 3\,R_1/4$.

To complete the proof, we will use the stability inequality together with the logarithmic cutoff trick to take advantage of the quadratic area growth. Define a cutoff function ψ_1 by

$$\psi_1 = \psi_1(\rho) = \begin{cases} \log(\rho/r_1)/\log\Omega & \text{on } S_{r_1,\Omega\,r_1}\,, \\ 1 & \text{on } S_{\Omega\,r_1,R_1/\Omega}\,, \\ -\log(\rho/R_1)/\log\Omega & \text{on } S_{R_1/\Omega,R_1}\,, \\ 0 & \text{otherwise}\,. \end{cases} \tag{II.1.20}$$

Using (II.1.3) and (II.1.19), we get

$$E(\psi_1) \leq C(m + R_1/r_1)/\log\Omega\,. \tag{II.1.21}$$

As in (II.1.15), we apply the stability inequality to $\chi_1\psi_1$ to get

$$\int |A|^2\chi_1^2\psi_1^2 \leq 2E(\psi_1) + 2E(\chi_1) \leq 2\,C(m + R_1/r_1)/\log\Omega + 2\tilde{C}\,R_1/r_1\,. \tag{II.1.22}$$

Combining (II.1.13) and (II.1.22) completes the proof. □

Using Lemma II.1.1, we show that large stable sectors have almost flat subsectors:

Corollary II.1.23. Given $\omega > 8, 1 > \epsilon > 0$, there exist m_1, Ω_1 so: Suppose $\gamma \subset B_{2\,r_1} \cap \Sigma$ is a curve with $1/(2\,r_1) < k_g < 2/r_1$, $\text{Length}(\gamma) = 32\,\pi\,m_1\,r_1$, $\text{dist}_\Sigma(S_{\Omega_1^2\,\omega\,r_1}(\gamma), \partial\Sigma) \geq r_1/2$. If there is a simple curve $\gamma^\partial \subset \Sigma$ with $\gamma \subset \gamma^\partial$, $\partial\gamma^\partial \subset \partial\Sigma$, and $\gamma_x \cap \gamma^\partial = \{x\}$ for $x \in \gamma$, then (after rotating $\mathbf{R}^3$) $S_{\Omega_1^2\,\omega\,r_1}(\gamma)$ contains a 2-valued graph Σ_d over $D_{2\,\omega\,\Omega_1\,r_1} \setminus D_{\Omega_1\,r_1/2}$ with gradient $\leq \epsilon/2$, $|A| \leq \epsilon/(2\,r)$, and $\text{dist}_{S_{\Omega_1^2\,\omega\,r_1}(\gamma)}(\gamma, \Sigma_d) < 2\,\Omega_1\,r_1$.

Proof. We will choose $\Omega_1 > 12$ and then set $m_1 = \omega\,\Omega_1^2\,\log\Omega_1$. By Lemma II.1.1 (with $\Omega = \Omega_1/6$, $R_1 = \Omega_1^2\,\omega\,r_1$, and $m = 32\,m_1/3$),

$$\int_{S_{\Omega_1\,r_1/6,6\,\Omega_1\,\omega\,r_1}(\gamma)} |A|^2 \leq C(\Omega_1^2\,\omega + m_1/\log\Omega_1) = 2\,C\,m_1/\log\Omega_1\,. \tag{II.1.24}$$

Fix m_1 disjoint curves $\gamma_1, \ldots, \gamma_{m_1} \subset \gamma$ with $\text{Length}(\gamma_i) = 32\,\pi\,r_1$. By (II.1.24) and since the $S_{\Omega_1^2\,\omega\,r_1}(\gamma_i)$ are pairwise disjoint, there exists γ_i with

$$\int_{S_{\Omega_1\,r_1/6,6\,\Omega_1\,\omega\,r_1}(\gamma_i)} |A|^2 \leq 2\,C/\log\Omega_1\,. \tag{II.1.25}$$

To deduce the corollary from (II.1.25) we need a few standard facts. First, define a map $\Phi : [0, \Omega_1^2\omega r_1] \times_{\rho/(2\,r_1)+1} [0, \text{Length}(\gamma)] \to \Sigma$ by $\Phi(\rho, x) = \gamma_x(\rho)$. By the Riccati comparison argument (using $\text{K}_\Sigma \leq 0$ and $k_g > 1/(2\,r_1)$ on γ),

$$\Phi \text{ is distance nondecreasing and } k_g > \frac{1}{\rho + 2\,r_1}\,. \tag{II.1.26}$$

Second, let $\gamma_i/2 \subset \gamma_i$ be the subcurve of length $16\,\pi\,r_1$ with $\text{dist}_\gamma(\gamma_i/2, \partial\gamma_i) = 8\,\pi\,r_1$. Since $k_g > 1/(2\,r_1)$ on γ, we have $\int_{\gamma_i/2} k_g > 8\,\pi$. By (II.1.7), $\int_{S_{\Omega_1^2\,\omega\,r_1}(\gamma_i/2)\cap\{\rho=t\}} k_g$ is monotone nondecreasing. In particular, we can choose a curve $\tilde\gamma \subset \gamma_i/2$ with

$$\int_{S_{\Omega_1^2\,\omega\,r_1}(\tilde\gamma)\cap\{\rho=\Omega_1\,r_1/3\}} k_g = 8\,\pi\,. \tag{II.1.27}$$

Set $S = S_{\Omega_1\,r_1/3,3\,\Omega_1\,\omega\,r_1}(\tilde\gamma)$ and $\hat\gamma = S \cap \{\rho = \Omega_1\,r_1/3\}$.

Third, by the Gauss-Bonnet theorem, (II.1.25), and (II.1.27), (for Ω_1 large)

$$8\,\pi \leq \int_{S\cap\{\rho=t\}} k_g \leq 8\,\pi + \int_S |A|^2/2 \leq 8\,\pi + C/\log\Omega_1 \leq 9\,\pi\,. \tag{II.1.28}$$

Note also that, by (II.1.26) and (II.1.28), $\text{Length}(S \cap \{\rho = t\}) \leq 9\,\pi\,(t + 2\,r_1) \leq 14\,\pi\,t$.

Finally, observe that, by stability, (II.1.25), and using (II.1.26), the meanvalue theorem gives for $y \in S$

$$\sup_{\mathcal{B}_{\rho(y)/3}(y)} |A|^2 \leq C_1\,\rho^{-2}(y)/\log\Omega_1\,. \tag{II.1.29}$$

Integrating (II.1.29) along rays and level sets of ρ, we get

$$\max_{x,y\in S} \text{dist}_{\mathbf{S}^2}(\mathbf{n}(x), \mathbf{n}(y)) \leq C_2\,(\log\omega + 1)/\sqrt{\log\Omega_1}\,. \tag{II.1.30}$$

We can now combine these facts to get the corollary. Choose Ω_1 so that $C_2\,(\log\omega + 1)/\sqrt{\log\Omega_1} < C_3\,\epsilon$. For C_3 small, after rotating $\mathbf{R}^3$, S is locally a graph over $\{x_3 = 0\}$ with gradient $\leq \epsilon/2$. Since $\tilde\gamma \subset B_{2\,r_1}$ and $\Omega_1 > 12$, we have $\hat\gamma \subset B_{2\,r_1+\Omega_1\,r_1/3} \subset B_{\Omega_1\,r_1/2}$. Choosing Ω_1 even larger and combining (II.1.26), (II.1.28), (II.1.29), and (II.1.30), we see that (the

orthogonal projection) $\Pi(\tilde{\gamma})$ is a convex planar curve with total curvature at least $7\,\pi$, so that its Gauss map covers $\mathbf{S}^1$ three times. Given $x \in \tilde{\gamma}$, set $\tilde{\gamma}_x = S \cap \gamma_x$. By (II.1.29), $\tilde{\gamma}_x$ has total (extrinsic geodesic) curvature at most $C_2\,\log\omega/\sqrt{\log\Omega_1} < C_3\,\epsilon$ and hence $\tilde{\gamma}_x$ lies in a narrow cone centered on its tangent ray at $\tilde{x} = \tilde{\gamma}_x \cap \hat{\gamma}$. For C_3 small, this implies that $\tilde{\gamma}_x$ does not rotate and

$$|\Pi(\tilde{x}) - \Pi(\tilde{\gamma}_x \cap \{\rho = t\})| \geq 9\,(t - \Omega_1\,r_1/3)/10\,. \tag{II.1.31}$$

Hence, $\Pi(\partial\tilde{\gamma}_x \setminus \{\tilde{x}\}) \notin D_{2\,\omega\,\Omega_1\,r_1}$ which gives Σ_d and also $\text{dist}_{S_{\Omega_1^2\,\omega\,r_1}(\gamma)}(\gamma, \Sigma_d) < 2\,\Omega_1\,r_1$. □

Remark II.1.32. For convenience, we assumed that $k_g < 2/r_1$ in Corollary II.1.23. This was used only to apply Lemma II.1.1 and it was used there only to bound $\int_\gamma k_g$ in (II.1.9).

Recall that a domain Ω is 1/2-stable if and only if, for all $\phi \in C_0^{0,1}(\Omega)$, we have the 1/2-stability inequality:

$$1/2 \int |A|^2\phi^2 \leq \int |\nabla\phi|^2\,. \tag{II.1.33}$$

Note that the interior curvature estimate of [Sc] extends to 1/2-stable surfaces.

In light of Remark II.1.32, it is easy to get the following analog of Corollary II.1.23:

Corollary II.1.34. Given $\omega > 8, 1 > \epsilon > 0, C_0$, N, there exist m_1, Ω_1 so: Suppose Σ is an embedded minimal disk, $\gamma \subset \partial\mathcal{B}_{r_1}(y) \subset \Sigma$ is a curve, $\int_\gamma k_g < C_0\,m_1$, $\text{Length}(\gamma) = m_1\,r_1$. If $\mathcal{T}_{r_1/8}(S_{\Omega_1^2\,\omega\,r_1}(\gamma))$ is 1/2-stable, then (after rotating $\mathbf{R}^3$) $S_{\Omega_1^2\,\omega\,r_1}(\gamma)$ contains an N-valued graph Σ_N over $D_{\omega\,\Omega_1\,r_1} \setminus D_{\Omega_1\,r_1}$ with gradient $\leq \epsilon$, $|A| \leq \epsilon/r$, and $\text{dist}_{S_{\Omega_1^2\,\omega\,r_1}(\gamma)}(\gamma, \Sigma_N) < 4\,\Omega_1\,r_1$.

Note that, in Corollary II.1.34, $k_g \geq 1/r_1$ and the injectivity of the exponential map both follow immediately from comparison theorems.

II.2. The sublinear growth

This section gives an elementary gradient estimate for multi-valued minimal graphs which is applied to show that the separation between the sheets of certain minimal graphs grows sublinearly; see fig. 11. The example to keep in mind is the portion of a (rescaled) helicoid in a slab between two cylinders about the vertical axis. This gives (two) multi-valued graphs over an annulus; removing a vertical half-plane through the axis cuts these into sheets which remain a bounded distance apart.

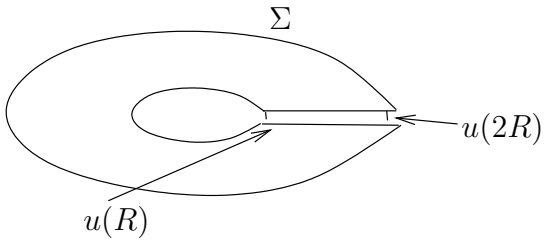

FIGURE 11. The sublinear growth of the separation u of the multi-valued graph Σ: $u(2R) \leq 2^\alpha\,u(R)$ with $\alpha < 1$.

The next lemma and corollary construct the cutoff function needed in our gradient estimate.

Lemma II.2.1. Given $N > 36/(1-\mathrm{e}^{-1/3})^2$, there exists a function $0 \leq \phi \leq 1$ on $\mathcal{P}$ with $E(\phi) \leq 4\,\pi/\log N$,

$$\phi = \begin{cases} 1 & \text{if } R/\mathrm{e} \leq \rho \leq \mathrm{e}\,R \text{ and } |\theta| \leq 3\,\pi\,, \\ 0 & \text{if } \rho \leq \mathrm{e}^{-N}\,R \text{ or } \mathrm{e}^{N}\,R \leq \rho \text{ or } |\theta| \geq \pi\,N\,. \end{cases} \tag{II.2.2}$$

Proof. After rescaling, we may assume that $R = 1$. Since energy is conformally invariant on surfaces, composing with $z^{3\,N}$ implies that (II.2.2) is equivalent to $E(\phi) \leq 4\,\pi/\log N$,

$$\phi = \begin{cases} 1 & \text{if } |\log\rho| < 1/(3\,N) \text{ and } |\theta| \leq \pi/N\,, \\ 0 & \text{if } |\log\rho| > 1/3 \text{ or } |\theta| \geq \pi/3\,. \end{cases} \tag{II.2.3}$$

This is achieved (with $E(\phi) = 2\,\pi/\log[N(1-\mathrm{e}^{-1/3})/6]$) by setting

$$\phi = \begin{cases} 1 & \text{on } \mathcal{B}_{6/N}(1,0)\,, \\ 1 - \frac{\log[N\,\mathrm{dist}_{\mathcal{P}}((1,0),\cdot)/6]}{\log[N(1-\mathrm{e}^{-1/3})/6]} & \text{on } \mathcal{B}_{1-\mathrm{e}^{-1/3}}(1,0) \setminus \mathcal{B}_{6/N}(1,0)\,, \\ 0 & \text{otherwise}\,. \end{cases} \tag{II.2.4}$$

□

Given an N-valued graph Σ, let $\Sigma^{\theta_1,\theta_2}_{r_3,r_4} \subset \Sigma$ be the subgraph (cf. (0.1)) over

$$\{(\rho,\theta)\,|\,r_3 \leq \rho \leq r_4,\, \theta_1 \leq \theta \leq \theta_2\}\,. \tag{II.2.5}$$

Corollary II.2.6. Given $\epsilon_0, \tau > 0$, there exists $N > 0$ so if $\Sigma \subset \mathbf{R}^3$ is an N-valued graph over $D_{\mathrm{e}^N\,R} \setminus D_{\mathrm{e}^{-N}\,R}$ with gradient $\leq \tau$, then there is a cutoff function $0 \leq \phi \leq 1$ on Σ with $E(\phi) \leq \epsilon_0$, $\phi|_{\partial\Sigma} = 0$, and

$$\phi \equiv 1 \text{ on } \Sigma^{-\pi,3\pi}_{R/2,5R/2}\,. \tag{II.2.7}$$

Proof. Since $\Sigma^{-\pi,3\pi}_{R/2,5R/2} \subset \Sigma^{-3\pi,3\pi}_{R/\mathrm{e},\mathrm{e}R}$ and the projection from Σ to $\mathcal{P}$ is bi-Lipschitz with bi-Lipschitz constant bounded by $\sqrt{1+\tau^2}$, the corollary follows from Lemma II.2.1. □

If $u > 0$ is a solution of the Jacobi equation $\Delta u = -|A|^2 u$ on Σ, then $w = \log u$ satisfies

$$\Delta w = -|\nabla w|^2 - |A|^2\,. \tag{II.2.8}$$

The Bochner formula, (II.2.8), $\mathrm{K}_\Sigma = -|A|^2/2$, and the Cauchy-Schwarz inequality give

$$\begin{aligned} \Delta|\nabla w|^2 &= 2\,|\mathrm{Hess}_w|^2 + 2\langle \nabla w, \nabla\Delta w\rangle - |A|^2\,|\nabla w|^2 \\ &\geq 2\,|\mathrm{Hess}_w|^2 - 4\,|\nabla w|^2\,|\mathrm{Hess}_w| - 4\,|\nabla w|\,|A|\,|\nabla A| - |A|^2\,|\nabla w|^2 \\ &\geq -2\,|\nabla w|^4 - 3\,|A|^2\,|\nabla w|^2 - 2\,|\nabla A|^2\,. \end{aligned} \tag{II.2.9}$$

Since the Jacobi equation is the linearization of the minimal graph equation over Σ, analogs of (II.2.8) and (II.2.9) hold for solutions of the minimal graph equation over Σ. In particular, standard calculations give the following analog of (II.2.8):

Lemma II.2.10. There exists $\delta_g > 0$ so if Σ is minimal and u is a positive solution of the minimal graph equation over Σ (i.e., $\{x+u(x)\,\mathbf{n}_\Sigma(x)\,|\,x \in \Sigma\}$ is minimal) with $|\nabla u| + |u|\,|A| \leq \delta_g$, then $w = \log u$ satisfies on Σ

$$\Delta w = -|\nabla w|^2 + \mathrm{div}(a\nabla w) + \langle \nabla w, a\nabla w\rangle + \langle b, \nabla w\rangle + (c-1)|A|^2\,, \tag{II.2.11}$$

for functions a_{ij}, b_j, c on Σ with $|a|, |c| \leq 3\,|A|\,|u| + |\nabla u|$ and $|b| \leq 2\,|A|\,|\nabla u|$.

The following gives an improved gradient estimate, and consequently an improved bound for the growth of the separation between the sheets, for multi-valued minimal graphs:

Proposition II.2.12. Given $\alpha > 0$, there exist $\delta_p > 0, N_g > 5$ so: Let Σ be an N_g-valued minimal graph over $D_{\mathrm{e}^{N_g} R} \setminus D_{\mathrm{e}^{-N_g} R}$ with gradient ≤ 1. If $0 < u < \delta_p R$ is a solution of the minimal graph equation over Σ with $|\nabla u| \leq 1$, then for $R \leq s \leq 2R$

$$\sup_{\Sigma^{0,2\pi}_{R,2R}} |A_\Sigma| + \sup_{\Sigma^{0,2\pi}_{R,2R}} |\nabla u|/u \leq \alpha/(4R)\,, \tag{II.2.13}$$

$$\sup_{\Sigma^{0,2\pi}_{R,s}} u \leq (s/R)^\alpha \sup_{\Sigma^{0,2\pi}_{R,R}} u\,. \tag{II.2.14}$$

Proof. Fix $\epsilon_E > 0$ (to be chosen depending only on α). Corollary II.2.6 gives N (depending only on ϵ_E) and a function $0 \leq \phi \leq 1$ with compact support on $\Sigma^{-N\pi,N\pi}_{\mathrm{e}^{-N}R,\mathrm{e}^N R}$

$$E(\phi) \leq \epsilon_E \text{ and } \phi \equiv 1 \text{ on } \Sigma^{-\pi,3\pi}_{R/2,5R/2}\,. \tag{II.2.15}$$

Set $N_g = N + 1$, so that $\mathrm{dist}_\Sigma(\Sigma^{-N\pi,N\pi}_{\mathrm{e}^{-N}R,\mathrm{e}^N R}, \partial\Sigma) > \mathrm{e}^{-N} R/2$ and hence $|A| \leq C\mathrm{e}^N/R$ on $\Sigma^{-N\pi,N\pi}_{\mathrm{e}^{-N}R,\mathrm{e}^N R}$. Now fix $x \in \Sigma^{0,2\pi}_{R,2R}$. Substituting ϕ into the stability inequality, (II.2.15) bounds the total second fundamental form of $\Sigma^{-\pi,3\pi}_{R/2,5R/2}$ by ϵ_E. Hence, by elliptic estimates for the minimal graph equation,

$$\sup_{\mathcal{B}_{3R/8}(x)} (R^2 |\nabla A_\Sigma|^2 + |A_\Sigma|^2) \leq C\,\epsilon_E R^{-2}\,. \tag{II.2.16}$$

Since Σ and the graph of u are (locally) graphs with bounded gradient, it is easy to see that

$$\sup_{\Sigma^{-N\pi,N\pi}_{\mathrm{e}^{-N}R,\mathrm{e}^N R}} |\nabla u| \leq C\,\mathrm{e}^N \sup_\Sigma |u|/R \leq C\,\mathrm{e}^N\,\delta_p\,. \tag{II.2.17}$$

Set $w = \log u$. Choose $\delta_p > 0$ (depending only on N), so that (II.2.17) implies that w satisfies (II.2.11) on $\Sigma^{-N\pi,N\pi}_{\mathrm{e}^{-N}R,\mathrm{e}^N R}$ with $|a|, |b|/|A|, |c| \leq 1/4$. Applying Stokes' theorem to $\mathrm{div}(\phi^2\nabla w - \phi^2 a \nabla w)$ and using the absorbing inequality gives

$$\int_{\mathcal{B}_{R/2}(x)} |\nabla w|^2 \leq \int \phi^2 |\nabla w|^2 \leq C\,E(\phi) \leq C\,\epsilon_E\,. \tag{II.2.18}$$

Combining (II.2.11) and (II.2.16), an easy calculation (as in (II.2.9)) shows that on $\mathcal{B}_{3R/8}(x)$

$$\Delta |\nabla w|^2 \geq -C\,|\nabla w|^4 - C\,\epsilon_E\,R^{-2}\,|\nabla w|^2 - C\,\epsilon_E\,R^{-4}\,. \tag{II.2.19}$$

By the rescaling argument of [CiSc] (using the meanvalue inequality), (II.2.18) and (II.2.19) imply a pointwise bound for $|\nabla w|^2$ on $\mathcal{B}_{R/4}(x)$; combining this with (II.2.16) gives (II.2.13) for ϵ_E small. Integrating (II.2.13) and using that $(s-R)/R \leq 2\,\log(s/R)$ gives (II.2.14). □

II.3. Extending multi-valued graphs in stable disks

Throughout this section $\Sigma \subset B_{R_0}$ is a stable embedded minimal disk with $\partial\Sigma \subset B_{r_0} \cup \partial B_{R_0} \cup \{x_1 = 0\}$ and $\partial\Sigma \setminus \partial B_{R_0}$ connected. Fix $0 < \tau_k < 1/4$ so if Σ_g is a multi-valued minimal graph over $D_{2R} \setminus D_{R/2}$ with gradient $\leq \tau_k$, then $\Pi^{-1}(\partial D_R) \cap \Sigma_g$ has geodesic curvature $1/(2R) < k_g < 2/R$ (with respect to the outward normal).

The next corollary shows that for certain such Σ containing multi-valued graphs, the middle sheet Σ^M extends to a larger scale. The main point is to apply Corollary II.1.23 to get two 2-valued graphs on a larger scale with Σ^M pinched between them. We first use the convex hull property to construct the curves γ_j^∂ needed for Corollary II.1.23.

Corollary II.3.1. Given $\omega, m > 1$, $1/4 \geq \epsilon > 0$, there exist Ω_1, m_0, δ so for r_0, r_2, R_2, R_0 with $4\,\Omega_1\, r_0 \leq 4\,\Omega_1\, r_2 < R_2 < R_0/(4\,\Omega_1\,\omega)$: Suppose $\Sigma_g \subset \Sigma$ is an m_0-valued graph over $D_{R_2} \setminus D_{r_2}$ with gradient $\leq \tau_k$, $\Pi^{-1}(D_{r_2}) \cap \Sigma_g \subset \{|x_3| \leq r_2/2\}$, and separation between the top and bottom sheets $\leq \delta\, R_2$ over ∂D_{R_2}. If a curve $\eta \subset \Pi^{-1}(D_{r_2}) \cap \Sigma \setminus \partial B_{R_0}$ connects Σ_g to $\partial\Sigma \setminus \partial B_{R_0}$, then Σ^M extends to an m-valued graph over $D_{\omega\, R_2} \setminus D_{r_2}$ with gradient ≤ 1 and $|A| \leq \epsilon/r$ over $D_{\omega\, R_2} \setminus D_{R_2}$.

Proof. First, we set up the notation. Let $\Omega_1, m_1 > 1$ be given by Corollary II.1.23. Assume that $\Omega_1^2\,\omega, m, m_1 \in \mathbf{Z}$. Set $m_0 = 24\,\Omega_1^2\,\omega + 32\,m_1 + m + 1$ and $\gamma = \Pi^{-1}(\partial D_{R_2/\Omega_1}) \cap \Sigma_g$. Since $\Pi^{-1}(D_{r_2}) \cap \Sigma_g \subset \{|x_3| \leq r_2/2\}$, the gradient bound gives for $r_2 \leq R \leq R_2$

$$\max_{\Pi^{-1}(\partial D_R) \cap \Sigma_g} |x_3| \leq r_2/2 + \tau_k\,(R - r_2) \leq R/2\,, \tag{II.3.2}$$

so that $\gamma \subset B_{2R_2/\Omega_1}$. By the definition of τ_k, $\Omega_1/(2\,R_2) < k_g < 2\,\Omega_1/R_2$ on γ. Arguing on part of Σ itself, by the convex hull property, there are m_0 components of $\gamma \cap \{x_1 \geq R_2/(2\,\Omega_1)\}$ which are in distinct components of $\Sigma \cap \{x_1 \geq R_2/(2\,\Omega_1)\}$. Hence, see fig. 12, there are m_0 distinct $y_i \in \gamma$ and (nodal) curves $\sigma_0, \ldots, \sigma_{m_0-1} \subset \{x_1 = R_2/\Omega_1\} \cap \Sigma$ with $\partial\sigma_i = \{y_i, z_i\}$, $\sigma_i \cap \gamma = \{y_i\}$, $z_i \in \partial\Sigma \cap \{x_1 = R_2/\Omega_1\} \subset \partial B_{R_0}$, and for $i \neq j$

$$\mathrm{dist}_\Sigma(\sigma_i, \sigma_j) > R_2/\Omega_1\,. \tag{II.3.3}$$

Order the σ_i's using the ordering of the y_i's in γ and set $i_1 = 0$, $i_2 = 8\,\Omega_1^2\,\omega + 16\,m_1$, $i_3 = 16\,\Omega_1^2\,\omega + 16\,m_1 + m$, and $i_4 = m_0 - 1$. Let $\gamma_1, \gamma_2, \gamma_3 \subset \gamma$ be the curves from $y_{4\,\Omega_1^2\,\omega}$ to $y_{4\,\Omega_1^2\,\omega + 16\,m_1}$, from $y_{12\,\Omega_1^2\,\omega + 16\,m_1}$ to $y_{12\,\Omega_1^2\,\omega + 16\,m_1 + m}$, and from $y_{20\,\Omega_1^2\,\omega + 16\,m_1 + m}$ to $y_{20\,\Omega_1^2\,\omega + 32\,m_1 + m}$, respectively. Hence, $\gamma_1, \gamma_2, \gamma_3 \subset \gamma$ are $16\,m_1$-, m-, $16\,m_1$-valued graphs, respectively, with γ_2 centered on Σ^M, each γ_j between y_{i_j} and $y_{i_{j+1}}$, and for $j = 1, 2, 3$

$$\min_{\{k\,|\,y_k \in \gamma_j\}} \{|i_j - k|, |i_{j+1} - k|\} \geq 4\,\Omega_1^2\,\omega\,. \tag{II.3.4}$$

Next, we construct the curves γ_j^∂ needed to apply Corollary II.1.23 to each γ_j. We will also use (II.3.3) and (II.3.4) to separate the γ_j's. For $k_1 < k_2$, let $\gamma(k_1, k_2) \subset \Sigma$ be the union of σ_{k_1}, σ_{k_2}, and the curve in γ from y_{k_1} to y_{k_2}. Since Σ is a disk, $\partial\gamma(k_1, k_2) \subset \partial\Sigma$, and $\partial\Sigma \setminus \partial B_{R_0}$ is connected, one component $\Sigma(k_1, k_2)$ of $\Sigma \setminus \gamma(k_1, k_2)$ has $\partial\Sigma(k_1, k_2) \cap \partial\Sigma \subset \partial B_{R_0}$. Using that the σ_i's do not cross η, it is easy to see that $\mathbf{n}_\gamma$ points into $\Sigma(k_1, k_2)$ and

$$\Sigma(j_1, j_2) \cap \Sigma(k_1, k_2) = \Sigma(\max\{j_1, k_1\}, \min\{j_2, k_2\})\,, \tag{II.3.5}$$

where, by convention, $\Sigma(k_1, k_2) = \emptyset$ if $k_1 > k_2$. Set $\gamma_j^\partial = \gamma(i_j, i_{j+1})$ and note that $\gamma_j \subset \gamma_j^\partial$ and $\partial\gamma_j^\partial \subset \partial\Sigma$. Set $S_j = S_{\Omega_1\,\omega\,R_2}(\gamma_j)$. By (II.3.4) and (II.3.5), any curve $\tilde\eta \subset \Sigma(i_j, i_{j+1})$ from γ_j to $\gamma_j^\partial \setminus (\gamma \cup \partial B_{R_0})$ hits at least $4\,\Omega_1^2\,\omega$ of the σ_i's and so, by (II.3.3), $\mathrm{Length}(\tilde\eta) > 2\,\Omega_1\,\omega\,R_2$. Combining this with $R_0 > 4\Omega_1\,\omega\,R_2$, we get

$$\mathrm{dist}_{\Sigma(i_j, i_{j+1})}(\gamma_j, \partial\Sigma(i_j, i_{j+1}) \setminus \gamma_j) > 2\,\Omega_1\,\omega\,R_2\,. \tag{II.3.6}$$

Fix $x \in \gamma_j$ and γ_x (the geodesic normal to γ_j at x and of length $\Omega_1\,\omega\,R_2$). By (II.0.23), the first point (after x) where γ_x hits $\partial\Sigma(i_j, i_{j+1})$ cannot be in γ. Consequently, (II.3.6) implies that $\gamma_x \subset \Sigma(i_j, i_{j+1})$ so $\gamma_x \cap \gamma_j^{\partial} = \{x\}$ and γ_j^{∂} separates S_j from $S_k \cup \mathcal{T}_{R_2/(2\,\Omega_1)}(\partial\Sigma)$ for $j \neq k$.

The rest of the proof (see fig. 13) is to sandwich Σ^M between two graphs that will be given by Corollary II.1.23 and then deduce from stability that Σ^M itself extends to a graph. Namely, applying Corollary II.1.23 to γ_1, γ_3 (with $r_1 = R_2/\Omega_1$), we get 2-valued graphs $\Sigma_{d,1} \subset S_1$, $\Sigma_{d,3} \subset S_3$ over $B_{2\,\omega\,R_2} \cap P_i \setminus B_{R_2/2}$ $(i = 1, 3)$ with $|A| \leq \epsilon/(2\,r)$ and gradient $\leq \epsilon/2 \leq 1/8$. Here P_i is a plane through 0. Using $|A| \leq \epsilon/(2\,r)$ and $\operatorname{dist}_{S_i}(\gamma, \Sigma_{d,i}) < 2\,R_2$, it is easy to see that $\Sigma_{d,i} \cap \Sigma_g \neq \emptyset$. Hence, $\Sigma_{d,i}$ contains a 3/2-valued graph Σ_i over $D_{3\,\omega\,R_2/2} \setminus D_{2\,R_2/3}$ with gradient $\leq \tan\left(\tan^{-1}(1/4) + 2\tan^{-1}(1/8)\right) < 3/4$. By construction, Σ^M is pinched between Σ_1, Σ_3 which are graphs over each other with separation $\leq \omega^C\,\delta\,R_2$ (by the Harnack inequality). Since Σ is stable, it follows that if δ is small, then Σ^M extends to an m-valued graph Σ_2 over $D_{5\,\omega\,R_2/4} \setminus D_{4\,R_2/5}$ with Σ_2 between Σ_1 and Σ_3. In particular, Σ_2 is a graph over Σ_1. Finally, using that Σ_1 is a graph with gradient $\leq 3/4$ and $|A| \leq \epsilon/(2\,r)$, we get that Σ_2 is a graph with gradient ≤ 1 and $|A| \leq \epsilon/r$ (cf. Lemma I.0.9). □

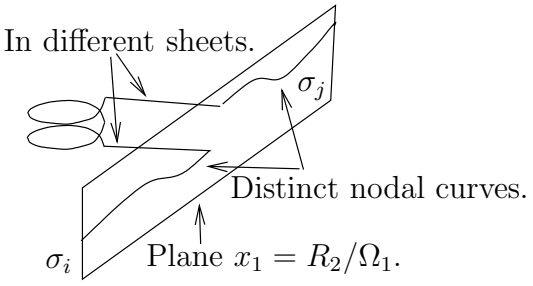

FIGURE 12. The proof of Corollary II.3.1: The nodal curves.

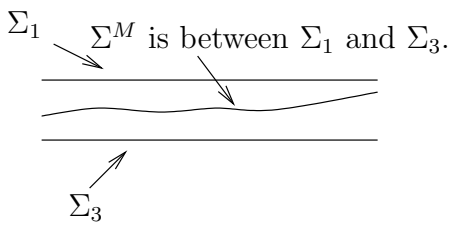

FIGURE 13. The proof of Corollary II.3.1: Sandwiching between two graphical pieces.

Combining this and Proposition II.2.12, Σ^M extends with separation growing sublinearly:

Corollary II.3.7. Given $1/4 \geq \epsilon > 0$, there exist $\Omega_0, m_0, \delta_0 > 0$ so for any r_0, r_2, R_2, R_0 with $\Omega_0\,r_0 \leq \Omega_0\,r_2 < R_2 < R_0/\Omega_0$: Suppose $\Sigma_g \subset \Sigma$ is an m_0-valued graph over $D_{R_2} \setminus D_{r_2}$ with gradient $\leq \tau_1 \leq \tau_k$, $\Pi^{-1}(D_{r_2}) \cap \Sigma_g \subset \{|x_3| \leq r_2/2\}$, and separations between the top and bottom sheets of $\Sigma^M (\subset \Sigma_g)$ and Σ_g are $\leq \delta_1\,R_2$ and $\leq \delta_0\,R_2$, respectively, over ∂D_{R_2}. If a curve $\eta \subset \Pi^{-1}(D_{r_2}) \cap \Sigma \setminus \partial B_{R_0}$ connects Σ_g to $\partial\Sigma \setminus \partial B_{R_0}$, then Σ^M extends as a graph over $D_{2\,R_2} \setminus D_{r_2}$ with gradient $\leq \tau_1 + 3\,\epsilon$, $|A| \leq \epsilon/r$ over $D_{2\,R_2} \setminus D_{R_2}$, and, for $R_2 \leq s \leq 2\,R_2$, separation $\leq (s/R_2)^{1/2}\,\delta_1\,R_2$ over $D_s \setminus D_{R_2}$.

Proof. Let $\delta_p > 0, N_g > 5$ be given by Proposition II.2.12 with $\alpha = 1/2$. Let $\Omega_1, m_0, \delta > 0$ be given by Corollary II.3.1 with $m = N_g + 3$ and $\omega = 2\,\mathrm{e}^{N_g}$. We will set $\delta_0 = \delta_0(\delta, \delta_p, N_g)$ with $\delta > \delta_0 > 0$ and $\Omega_0 = 4\,\Omega_1\,\mathrm{e}^{N_g}$. By Corollary II.3.1, Σ^M extends to a graph $\Sigma^{-(N_g+3)\pi,(N_g+3)\pi}_{r_2, 2\,\mathrm{e}^{N_g}\,R_2}$ of a function v with $|\nabla v| \leq 1$ and $|A| \leq \epsilon/r$ over $D_{2\,\mathrm{e}^{N_g}\,R_2} \setminus D_{R_2}$. Integrating $|\nabla|\nabla v|| \leq |A|\,(1 + |\nabla v|^2)^{3/2} \leq 2^{3/2}\,\epsilon/r$, we get that $|\nabla v| \leq \tau_1 + 4\,\epsilon\,\log 2 \leq \tau_1 + 3\,\epsilon$ on $D_{2R_2} \setminus D_{R_2}$.

For $\delta_0 = \delta_0(N_g, \delta_p) > 0$, writing Σ as a graph over itself and using the Harnack inequality, we get a solution $0 < u < \delta_p\,R_2$ of the minimal graph equation on an N_g-valued graph over $D_{\mathrm{e}^{N_g}\,R_2} \setminus D_{\mathrm{e}^{-N_g}\,R_2}$. Applying Proposition II.2.12 to u gives the last claim. □

The next lemma uses the Harnack inequality to show that if Σ^M extends with small separation, then so do the other sheets. The only complication is to keep track of $\partial\Sigma$.

Lemma II.3.8. Given $N \in \mathbf{Z}_+$, there exist $C_3, \delta_2 > 0$ so for $r_0 \leq s < R_0/8$: Suppose $\Sigma_g \subset \Sigma \cap \{|x_3| \leq 2\,s\}$ is an N-valued graph over $D_{2\,s} \setminus D_s$. If a curve $\eta \subset \Pi^{-1}(D_s) \cap \Sigma \setminus \partial B_{R_0}$ connects Σ_g to $\partial\Sigma \setminus \partial B_{R_0}$, and Σ^M extends graphically over $D_{4\,s} \setminus D_s$ with gradient $\leq \tau_2 \leq 1$ and separation $\leq \delta_3\, s \leq \delta_2\, s$, then Σ_g extends to an N-valued graph over $D_{3\,s} \setminus D_s$ with gradient $\leq \tau_2 + C_3\,\delta_3$ and separation between the top and bottom sheets $\leq C_3\,\delta_3\, s$.

Proof. Suppose N is odd (the even case is virtually identical). Fix $y_{-N}, \ldots, y_N \in \Sigma_g$ with y_j over $\{\rho = 2\,s,\, \theta = j\,\pi\}$. Let $\gamma_0, \gamma_2 \subset \Sigma^M$ be the graphs over $\{2s \leq \rho \leq 3s, \theta = 0\}$ and $\{2s \leq \rho \leq 3s, \theta = 2\,\pi\}$, respectively, with $\partial\gamma_0 = \{y_0, z_0\}$ and $\partial\gamma_2 = \{y_2, z_2\}$.

Arguing as in the proof of Corollary II.3.1, there are nodal curves $\sigma_{-N}, \ldots, \sigma_N \subset \{x_1 = -2\,s\} \cap \Sigma$ from y_j (for j odd) to ∂B_{R_0} so: (1) Any curve in $\Sigma \setminus \Pi^{-1}(\partial D_{2\,s})$ from z_0 to $\partial\Sigma \setminus \partial B_{R_0}$ hits either every σ_j with $j > 0$ or every σ_j with $j < 0$; (2) for $i < j$, σ_i and σ_j do not connect in $\Pi^{-1}(D_{4s}) \cap \{x_1 \leq -2\,s\} \cap \Sigma$; and (3) $\mathrm{dist}(\cup_j \sigma_j, \partial\Sigma \setminus \partial B_{R_0}) \geq s$. Note that (2) follows easily from the convex hull property when $i \neq -N$ or $j \neq N$; the case $i = -N$ and $j = N$ follows since Σ separates y_{-N}, y_N in $\Pi^{-1}(D_{4s}) \cap \{x_1 \leq -2\,s\}$.

By [Sc] and the Harnack inequality for the minimal graph equation, there exist $C_4, \delta_4 > 0$ so if $z_3, z_4 \in \Sigma \setminus \mathcal{T}_{s/4}(\partial\Sigma)$, $\Pi(z_3) = \Pi(z_4)$, and $0 < |z_3 - z_4| \leq \delta_5\, s \leq \delta_4\, s$, then $\mathcal{B}_{s/8}(z_4)$ is a graph over (a subset of) $\mathcal{B}_{s/7}(z_3)$ of a function $u > 0$ with $|\nabla u| \leq \min\{1/2, C_4\,\delta_5\}$. The lemma now follows easily by repeatedly applying this and using (1)–(3) to stay away from $\partial\Sigma$ until we have recovered all N sheets. □

II.4. Proof of Theorem II.0.21

Let again $\Sigma \subset B_{R_0}$ be a stable embedded disk with $\partial\Sigma \subset B_{r_0} \cup \partial B_{R_0} \cup \{x_1 = 0\}$ and $\partial\Sigma \setminus \partial B_{R_0}$ connected. We will use the notation of (II.2.5), so that $\Sigma^{0,2\pi}_{r_3,r_4}$ is an annulus with a slit as defined in [CM3]. An easy consequence of theorem 3.36 of [CM3] is:

Lemma II.4.1. Given $\tau_0 > 0$, there exists $0 < \epsilon_1 = \epsilon_1(\tau_0) < 1/24$ so: If $2r_0 \leq 1 < r_3 \leq R_0/2$ and $\Sigma^{0,2\pi}_{1,r_3} \subset \Sigma$ is the graph of a function u with $|\nabla u| \leq 1/12$, $\max_{\Sigma^{0,2\pi}_{1,1}}(|u| + |\nabla u|) \leq 2\,\epsilon_1$, $|A| \leq \epsilon_1/r$, and for $1 \leq t \leq r_3$ the separation over ∂D_t is $\leq 4\,\pi\,\epsilon_1\, t^{1/2}$, then $|\nabla u| \leq \tau_0$.

Lemma II.4.1 follows from theorem 3.36 of [CM3] and two facts. First, since Σ is a graph over a larger set in $\mathcal{P}$ (using stability and that $\partial\Sigma \subset B_{r_0} \cup \partial B_{R_0} \cup \{x_1 = 0\}$), the bound for the separation and estimates for the minimal graph equation over Σ give a bound for the difference in the two values of ∇u along the slit (cf. Proposition II.2.12). Second, theorem 3.36 of [CM3] actually applies directly to $B_{3r_3/4} \cap \Sigma^{0,2\pi}_{1,r_3} \setminus B_2$ to get $|\nabla u| \leq \tau_0/2$ on $D_{r_3/2} \setminus D_2$; integrating $|\nabla|\nabla u|| \leq |A|\,(1 + |\nabla u|^2)^{3/2} \leq 2\,\epsilon_1/r$ then gives $|\nabla u| \leq \tau_0$ on $D_{r_3} \setminus D_1$.

We will prove Theorem II.0.21 by repeatedly applying Corollary II.3.7 to extend Σ^M as a graph, Lemma II.4.1 to get an improved gradient bound, and then Lemma II.3.8 to extend additional sheets.

Proof. (of Theorem II.0.21). Set $\tau_0 = \min\{\tau, \tau_k, 1/24\}/2$ and let $0 < \epsilon_1 = \epsilon_1(\tau_0) < 1/72$ be given by Lemma II.4.1. Ω_0, m_0, δ_0 be given by Corollary II.3.7 (depending on ϵ_1) and $C_3, \delta_2 > 0$ be from Lemma II.3.8 with $N = m_0$. Set $N_1 = m_0$, $\Omega_1 = 2\,\Omega_0$, and choose $\epsilon > 0$

so:

$$\epsilon < \min\{\frac{\epsilon_1}{2},\, \frac{\tau_0}{4\,\pi\,2^{1/2}\,C_3},\, \frac{\delta_0}{2\,\pi\,2^{1/2}\,C_3},\, \frac{\delta_0}{2\,\pi\,m_0},\, \frac{\delta_2}{4\,\pi\,2^{1/2}}\}\,, \tag{II.4.2}$$

$\Pi^{-1}(D_{r_0}) \cap \Sigma_g \subset \{|x_3| \leq r_0/2\}$, and $|A| \leq \epsilon_1/r$ on $\Sigma^M \setminus B_{2\,r_0}$. To arrange the last condition, we use the gradient bound, stability, and second derivative estimates for the minimal graph equation (in terms of the gradient bound). Note that, using gradient $\leq \epsilon$, the separation between the top and bottom sheets of $\Sigma^{0,2\pi}_{r_0,1}$ and $\Sigma^{-m_0\pi,m_0\pi}_{r_0,1}$ over ∂D_t are at most $2\,\pi\,\epsilon\,t$ and $2\,\pi\,m_0\,\epsilon\,t$, respectively. Note also that $\Pi^{-1}(D_{3\,r_0}) \cap \Sigma_g \subset \{|x_3| \leq 3\,\epsilon\,r_0\}$.

(1) Apply Corollary II.3.7 (with $r_2 = r_0, R_2 = 1, \tau_1 = 2\,\tau_0$) to extend $\Sigma^{0,2\pi}_{r_0,1}$ to a graph $\Sigma^{0,2\pi}_{r_0,2}$ with gradient $\leq 2\,\tau_0 + 3\,\epsilon_1 < 1/12$, $|A| \leq \epsilon_1/r$ over $D_2 \setminus D_1$, and, for $1 \leq t \leq 2$,

$$\text{separation } \leq 2\,\pi\epsilon\,t^{1/2} \text{ over } \partial D_t\,. \tag{II.4.3}$$

(2) By Lemma II.4.1 (with $r_3 = 2$), $\Sigma^{0,2\pi}_{1,2}$ and hence $\Sigma^{0,2\pi}_{r_0,2}$ have gradient $\leq \tau_0$.

(3) By Lemma II.3.8 (with $N = m_0, s = 1/2, \tau_2 = \tau_0, \delta_3 = 4\,\pi\epsilon\,2^{1/2}$), $\Sigma^{0,2\pi}_{r_0,3/2}$ is contained in an m_0-valued graph $\Sigma^{-m_0\pi,m_0\pi}_{r_0,3/2} \subset \Sigma$ over $D_{3/2} \setminus D_{r_0}$ with gradient $\leq \tau_0 + C_3\,4\,\pi\epsilon\,2^{1/2} < 2\,\tau_0$ and separation $\leq C_3\,2\,\pi\epsilon\,2^{1/2} < \delta_0$.

Repeat (1)–(3) with: (1) $R_2 = 3/2$ to extend $\Sigma^{0,2\pi}_{r_0,3/2}$ to $\Sigma^{0,2\pi}_{r_0,3}$ with (II.4.3) holding for $1 \leq t \leq 3$, (2) $r_3 = 3$ so that $\Sigma^{0,2\pi}_{r_0,3}$ has gradient $\leq \tau_0$, (3) $s = 3/2$ to get $\Sigma^{-m_0\pi,m_0\pi}_{r_0,9/2} \subset \Sigma$, and then again (1) $R_2 = 9/2$, etc., giving the theorem. □

Part III. The general case of Theorem I.0.8

III.1. Constructing multi-valued graphs in disks in slabs

Using Part I, we show next that an embedded minimal disk in a slab contains a multi-valued graph if it is not a graph. We can therefore apply Part II to get almost flatness of a corresponding stable disk past the slab. This is needed when the minimal surface is not in a thin slab.

Proposition III.1.1. There exists $\beta > 0$ so: If $\Sigma^2 \subset B_{r_0} \cap \{|x_3| \leq \beta\,h\}$ is an embedded minimal disk, $\partial\Sigma \subset \partial B_{r_0}$, and a component Σ_1 of $B_{10\,h} \cap \Sigma$ is not a graph, then Σ contains an N-valued graph over $D_{r_0-2\,h} \setminus D_{(60+20\,N)\,h}$.

Proof. The proof has four steps. First we show, by using Lemma I.0.11 twice, that over a truncated sector in the plane, i.e., over

$$S_{s_1,s_2}(\theta_1,\theta_2) = \{(\rho,\theta)\,|\,s_1 \leq \rho \leq s_2,\, \theta_1 \leq \theta \leq \theta_2\} \tag{III.1.2}$$

we have 3 components of Σ. Second, we separate these by stable disks and order them by height. Third, we use Proposition I.0.16 to show that the "middle" component is a graph over a large sector. Fourth, we repeatedly use the appendix to extend the top and bottom components around the annulus and then Proposition I.0.16 to extend the middle component as a graph. This will give the desired multi-valued graph.

For $j = 1, 2$, let Σ_j be the component of $B_{20\,j\,h} \cap \Sigma$ containing Σ_1. By the maximum principle, each Σ_j is a disk. Rado's theorem gives $z_j \in \Pi^{-1}(\partial D_{(20\,j-10)\,h}) \cap \Sigma_j$ for $j = 1, 2$ where Σ is not graphical (see, e.g., [CM1]). Rotate $\mathbf{R}^2$ so $z_1, z_2 \in \{x_1 \geq 0\}$ and set $z =$

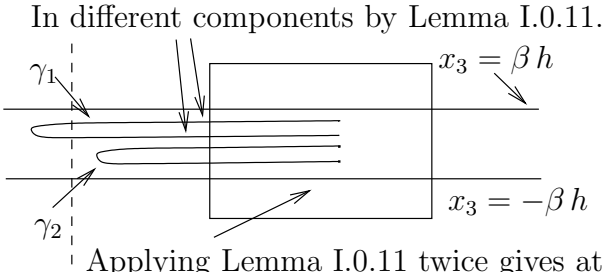

FIGURE 14. Proof of Proposition III.1.1: Step 1: Finding the 3 components.

$(r_0, 0, 0)$. Apply Lemma I.0.11 twice as in the first step of the proof of Proposition I.0.16 to get (see fig. 14): (1) Disjoint curves $\gamma_1, \gamma_2 \subset \Sigma$ with $\partial\gamma_k \subset \partial B_{r_0/2}$,

$$\gamma_k \subset B_{5\,h}(z_k) \cup T_h(\partial D_{(20\,k-10)\,h} \cap \{x_1 \geq 0\}) \cup T_h(\gamma_{0,z/2})\,, \tag{III.1.3}$$

and which are $C\,\beta\,h$-almost monotone in $T_h(\gamma_{0,z/2}) \setminus B_{20\,k\,h}$. (2) For $k = 1, 2$ and $y_0 \in \gamma_{0,z/2} \setminus B_{20\,k\,h}$, there are components $\Sigma'_{y_0,k,1} \neq \Sigma'_{y_0,k,2}$ of $B_{5\,h}(y_0) \cap \Sigma$ each containing points of $B_h(y_0) \cap \gamma_k$. It follows from (2) that, for $k = 1, 2$, there are components $\Sigma_{k,1}, \Sigma_{k,2}$ of $\Pi^{-1}(S_{42h,r_0-2\,h}(-3\pi/4, 3\pi/4)) \cap \Sigma$ with $\Sigma'_{z/2,k,i} \subset \Sigma_{k,i}$ and which do not connect in $\Pi^{-1}(S_{40h,r_0}(-7\pi/8, 7\pi/8)) \cap \Sigma$. Namely, Σ would otherwise contain a disk violating the maximum principle (as in the second step of Lemma I.0.11). The same argument gives $\Sigma_{i_1,i_1}, \Sigma_{i_2,i_2}, \Sigma_{i_3,i_3}$ which do not connect in

$$\Pi^{-1}(S_{40h,r_0}(-7\pi/8, 7\pi/8)) \cap \Sigma\,. \tag{III.1.4}$$

By the second step of Proposition I.0.16, if $\Sigma_{i,j}, \Sigma_{k,\ell}$ do not connect in $\Pi^{-1}(S_{40h,r_0}(-7\pi/8, 7\pi/8)) \cap \Sigma$, then there is a stable embedded disk Γ_α with $\partial\Gamma_\alpha \subset \Sigma$, $\Gamma_\alpha \cap \Sigma = \emptyset$, and a graph $\Gamma'_\alpha \subset \Gamma_\alpha$ over $S_{41h,r_0-h}(-13\pi/16, 13\pi/16)$ separating $\Sigma_{i,j}, \Sigma_{k,\ell}$. Applying this twice (and reordering the k_ℓ, i_ℓ), we get $\Gamma'_1 \subset \Gamma_1$, $\Gamma'_2 \subset \Gamma_2$ so each Σ_{k_ℓ,i_ℓ} is below Γ'_ℓ which is below $\Sigma_{k_{\ell+1},i_{\ell+1}}$. Let γ_1^t and γ_1^b be top and bottom components of $\cup_j \gamma_j \setminus B_{40\,h}$ intersecting $\partial B_{r_0/2}$. Since $\Sigma_1 \subset \Sigma_2$, a curve $\gamma_1^m \subset B_{40\,h} \cap \Sigma$ connects γ_1^t to γ_1^b.

See fig. 15. By a slight variation of Proposition I.0.16 (with $\gamma = \gamma_1^t \cup \gamma_1^m \cup \gamma_1^b$), the middle component Σ_{k_2,i_2} is a graph over $S_{42\,h,r_0-2\,h}(-3\pi/4, 3\pi/4)$. This variation follows from steps one and three of that proof (step two there constructs barriers Γ_i which were constructed here above).

See fig. 16. Corollary A.10 gives curves $\gamma_2^t, \gamma_2^b \subset (B_{44\,h} \cup T_h(\gamma_{0,(0,r_0,0)}) \setminus \Pi^{-1}(D_{42\,h})) \cap \Sigma$ from $\partial B_{43\,h} \cap \gamma_1^t$ and $\partial B_{43\,h} \cap \gamma_1^b$, respectively, to $\partial B_{r_0/2}$. In particular, γ_2^b is below Σ_{k_2,i_2} and γ_2^t is above Σ_{k_2,i_2}; i.e., Σ_{k_2,i_2} is still a middle component. Again by the maximum principle, this gives 3 distinct components of $\Pi^{-1}(S_{46\,h,r_0-2\,h}(-\pi/4, 5\pi/4)) \cap \Sigma$ which do not connect in $\Pi^{-1}(S_{45\,h,r_0}(-3\pi/8, 11\pi/8)) \cap \Sigma$. By Proposition I.0.16, Σ_{k_2,i_2} further extends as a graph over $S_{46\,h,r_0-2\,h}(-\pi/4, 5\pi/4)$, giving a graph $\Sigma^{-3\pi/4,5\pi/4}_{46\,h,r_0-2\,h}$ over $S_{46\,h,r_0-2\,h}(-3\pi/4, 5\pi/4)$. By Rado's theorem, this graph cannot close up. Repeating this with $\gamma_3^t, \gamma_3^b \subset (B_{49\,h} \cup T_h(\gamma_{0,(-r_0,0,0)}) \setminus \Pi^{-1}(D_{47\,h})) \cap \Sigma$, etc., eventually gives the proposition. □

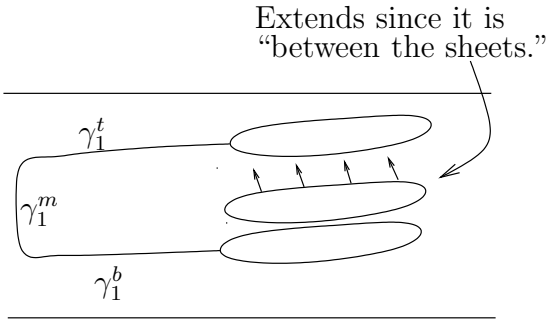

FIGURE 15. Proof of Proposition III.1.1: Step 3: Extending the middle component as a graph.

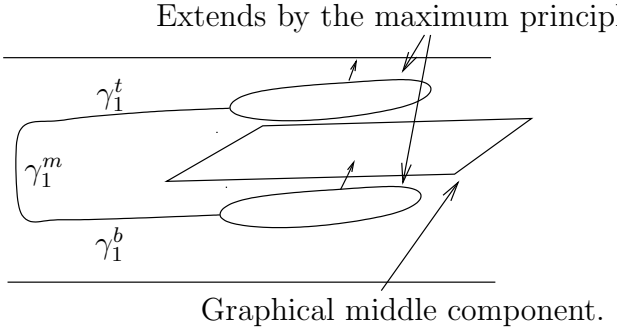

FIGURE 16. Proof of Proposition III.1.1: Step 4: Extending the top and bottom components by the maximum principle. They stay disjoint since the middle component is a graph separating them.

III.2. Proof of Theorem I.0.8

In this section, we generalize Proposition I.0.16 to when the minimal surface is not in a slab; i.e., we show Theorem I.0.8. $\Sigma^2 \subset B_{c_1\, r_0} \subset \mathbf{R}^3$ will be an embedded minimal disk, $\partial\Sigma \subset \partial B_{c_1\, r_0}$, $c_1 \geq 4$, and $y \in \partial B_{2\, r_0}$. $\Sigma_1, \Sigma_2, \Sigma_3$ will be distinct components of $B_{r_0}(y) \cap \Sigma$.

Lemma III.2.1. Given $\bar{\beta} > 0$, there exist $2\, c_2 < c_4 < c_3 \leq 1$ so: Let Σ_3' be a component of $B_{c_3\, r_0}(y) \cap \Sigma_3$ and $y_i \in B_{c_2\, r_0}(y) \cap \Sigma_i$ for $i = 1, 2$. If y_1, y_2 are in distinct components of $B_{c_4\, r_0}(y) \setminus \Sigma_3'$, then there are disjoint stable embedded minimal disks $\Gamma_1, \Gamma_2 \subset B_{r_0}(y) \setminus \Sigma$ with $\partial\Gamma_i = \partial\Sigma_i$, and (after a rotation) graphs $\Gamma_i' \subset \Gamma_i$ over $D_{3\, c_3\, r_0}(y)$ so that y_1, y_2, Σ_3' are each in their own component of $\Pi^{-1}(D_{3\, c_3\, r_0}(y)) \setminus (\Gamma_1' \cup \Gamma_2')$ and $\Gamma_1', \Gamma_2' \subset \{|x_3 - x_3(y)| \leq \bar{\beta}\, c_3\, r_0\}$.

Proof. This follows exactly as in the second step of the proof of Proposition I.0.16. □

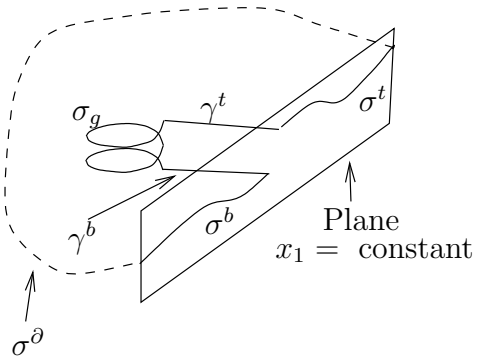

FIGURE 17. The curve γ_3 in the proof of Theorem I.0.8. ($\gamma_3 = \sigma^b \cup \gamma^b \cup \sigma_g \cup \gamma^t \cup \sigma^t \cup \sigma^\partial$.)

Proof. (of Theorem I.0.8). Let $N_1, \Omega_1, \epsilon > 0$ be given by Theorem II.0.21 (with $\tau = 1$). Assume that N_1 is even. Let $\beta > 0$ be from Proposition III.1.1. Set

$$\bar{\beta} = \min\left\{\beta_s,\, \epsilon,\, \epsilon/C_g,\, \beta/(6\,[60 + 20\,(N_1+3)])\right\}/(5\,\Omega_1)\,, \tag{III.2.2}$$

where β_s, C_g are from Lemma I.0.9. Let c_2, c_3, c_4 and $\Gamma_i' \subset \Gamma_i$ be given by Lemma III.2.1. Set $c_5 = (60 + 20\,(N_1+3))\bar{\beta}\,c_3/\beta$, so that $c_5 \leq c_3/(30\,\Omega_1)$. Finally, set $c_1 = 16\,\Omega_1$.

We will suppose that Σ_3' is not a graph at $z' \in \Sigma_3'$ and deduce a contradiction. Set $z = \Pi(z')$. Since Σ_3' separates y_1, y_2, it is in the slab between Γ_1', Γ_2'. Using Proposition III.1.1 (with $h = \bar{\beta}\,c_3\,r_0/\beta$) and (III.2.2), Σ contains an (N_1+3)-valued graph Σ_g over $D_{c_3\,r_0}(z) \setminus D_{c_5\,r_0}(z)$ and Σ_g is also in the slab. Let $\sigma_g \subset \Sigma_g$ be the (N_1+2)-valued graph over $\partial D_{c_5\,r_0}(z)$ (see fig. 17). Let E be the region in $\Pi^{-1}(D_{c_3\,r_0/2}(z) \setminus D_{c_3\,r_0/(2\,\Omega_1)}(z))$ between the sheets of the (concentric) (N_1+1)-valued subgraph of Σ_g.

The first step is to find a curve $\gamma_3 \subset \Sigma$ containing σ_g so any stable disk with boundary γ_3 is forced to spiral. γ_3 will have six pieces: σ_g, two segments, γ^t, γ^b, in Σ_g which are graphs over a portion of the $\{x_1 > x_1(z)\}$ part of the x_1-axis, two nodal curves, σ^t, σ^b, in $\{x_1 = \text{constant}\}$, and a segment σ^∂ in $\partial\Sigma$. Since Σ_g is a graph, there are graphs $\gamma^t, \gamma^b \subset \Sigma_g$ over a portion of the $\{x_1 > x_1(z)\}$ part of the x_1-axis from $\partial\sigma_g$ to $y^t, y^b \in \{x_1 = x_1(z) + 3\,c_5\,r_0\} \cap \Sigma$. By the maximum principle (as in the proof of Corollary II.3.1), there are nodal curves $\sigma^t, \sigma^b \subset \{x_1 = x_1(z) + 3\,c_5\,r_0\} \cap \Sigma$ from y^t, y^b, respectively, to $y_0^t, y_0^b \in \partial\Sigma$. Finally, connect y_0^t, y_0^b by a curve $\sigma^\partial \subset \partial\Sigma$ and set $\gamma_3 = \sigma^b \cup \gamma^b \cup \sigma_g \cup \gamma^t \cup \sigma^t \cup \sigma^\partial$. By [MeYa], there is a stable embedded disk $\Gamma \subset B_{c_1\,r_0} \setminus \Sigma$ with $\partial\Gamma = \gamma_3$. Note that $\partial\Gamma \setminus \partial B_{r_0}$ is connected.

We claim that σ^t, σ^b do not intersect between any two of the components $\{\sigma_i\}$ of $B_{(c_3-2c_5)\,r_0}(z) \cap \{x_1 = x_1(z) + 3\,c_5\,r_0\} \cap \Sigma_g$. If not, we can assume that a curve $\sigma \subset \sigma^t$ connects y^t to a point y_0 between σ_i, σ_{i+1}. By (a slight variation of) Proposition I.0.16, the portion Σ_{y_0} of Σ between the i-th and $(i+1)$-st sheets of $B_{(c_3-c_5)\,r_0}(z) \cap \Sigma_g \setminus \Pi^{-1}(D_{2\,c_5\,r_0}(z))$ is a graph (in fact, "all the way around"). Note that $B_{3\,c_5\,r_0}(z) \cap \Sigma_{y_0}$ and $B_{3\,c_5\,r_0}(z) \cap \Sigma_g$ are in the same component of $B_{3\,c_5\,r_0}(z) \cap \Sigma$, since else the stable disk between them given by [MeYa] would, using Lemma I.0.9, intersect Σ_g. We can therefore apply the maximum principle as in the proof of Corollary II.3.1 (i.e., the case $y_0 \in \sigma_j$ for some j) to get the desired contradiction.

We will show next that Γ contains an N_1-valued graph Γ_g over $D_{c_3\,r_0/2}(z) \setminus D_{c_3\,r_0/(2\,\Omega_1)}(z)$ with gradient $\leq \epsilon$, $\Pi^{-1}(D_{c_3\,r_0/(2\,\Omega_1)}(z)) \cap (\Gamma_g)^M \subset \{|x_3 - x_3(z)| \leq \epsilon\,c_3\,r_0/(2\,\Omega_1)\}$, and a curve $\eta \subset \Pi^{-1}(D_{c_3\,r_0/(2\,\Omega_1)}(z)) \cap \Gamma \setminus \partial B_{r_0}$ connects Γ_g to $\partial\Gamma \setminus \partial B_{r_0}$. By the previous paragraph,

$$\text{dist}_\Gamma(E \cap \Gamma, \partial\Gamma) > c_3\,r_0/(5\,\Omega_1)\,. \tag{III.2.3}$$

By (the proof of) Lemma I.0.9 (with $h = c_3\,r_0/(5\,\Omega_1)$ and $\beta = 5\,\Omega_1\,\bar{\beta}$), (III.2.2), and (III.2.3), we have that each component of $E \cap \Gamma$ is a multi-valued graph with gradient $\leq 5\,C_g\,\Omega_1\,\bar{\beta} \leq \epsilon$. Let $\sigma_c \subset E$ be a graph over $\partial D_{c_3\,r_0/(2\,\Omega_1)}(z)$. Using that σ_c separates $\Pi^{-1}(\partial D_{c_3\,r_0/(2\,\Omega_1)}(z)) \cap \gamma^t$ and $\Pi^{-1}(\partial D_{c_3\,r_0/(2\,\Omega_1)}(z)) \cap \gamma^b$ in the cylinder $\Pi^{-1}(\partial D_{c_3\,r_0/(2\,\Omega_1)}(z))$ (and the description of $\partial\Gamma$), there is a curve $\eta \subset \Pi^{-1}(D_{c_3\,r_0/(2\,\Omega_1)}(z)) \cap \Gamma \setminus \partial B_{r_0}$ from $\Gamma \cap \sigma_c$ to $\partial\Gamma \setminus \partial B_{r_0}$. Hence, since E is between the sheets of an (N_1+1)-valued graph, we get the desired Γ_g.

Combining all of this, Theorem II.0.21 gives a 2-valued graph $\Gamma_d \subset \Gamma$ over $D_{c_1\,r_0/(2\,\Omega_1)}(z) \setminus D_{c_3\,r_0/(2\,\Omega_1)}(z)$ with gradient ≤ 1. Let $\hat{\gamma}$ be the component of $B_{(2-2\,c_3)\,r_0} \cap \gamma$ intersecting B_{r_0}. Note that since $\partial\gamma = \{y_1, y_2\}$ is separated by the slab between Γ_1', Γ_2' and $\gamma \setminus B_{r_0}$ is $c_2\,r_0$-almost-monotone, Γ_d separates the endpoints of $\partial\hat{\gamma}$. Finally, as in the proof of Proposition I.0.16, we must have $\Gamma_d \cap \hat{\gamma} \neq \emptyset$. This contradiction completes the proof. □

Many variations of Theorem I.0.8 hold with almost the same proof. One such is:

Theorem III.2.4. There exist $d_1 \geq 8$ and $d_2 \leq 1$ so: Let $\Sigma^2 \subset B_{d_1\, r_0} \subset \mathbf{R}^3$ be an embedded minimal disk with $\partial\Sigma \subset \partial B_{d_1\, r_0}$ and let $y \in \partial D_{5\, r_0}$. Suppose that $\Sigma_1, \Sigma_2 \subset \Sigma$ are disjoint graphs over $D_{3r_0}(y)$ with gradient $\leq d_2$ and which intersect $B_{d_2 r_0}(y)$. If they can be connected in $B_{3r_0} \cap \Sigma$, then any component of $B_{r_0}(y) \cap \Sigma$ which lies between them is a graph.

Part IV. Extending multi-valued graphs off the axis

In this section $\Sigma \subset B_{R_0} \subset \mathbf{R}^3$ will be an embedded minimal disk with $\partial\Sigma \subset \partial B_{R_0}$. In contrast to the results of Part II, Σ is no longer assumed to be stable.

Note that, by [Sc], we can choose $d_3 > 4$ so that: If $\Gamma_0 \subset B_{d_3\, s}$ with $\partial\Gamma_0 \subset \partial B_{d_3\, s}$ is stable, then each component of $B_{4\, s} \cap \Gamma_0$ is a graph (over some plane) with gradient $\leq 1/2$.

Proof. (of Theorem 0.3). The proof has two steps. First, the proof of Theorem I.0.8 and Lemma II.3.8 give a stable disk $\Gamma \subset B_{R_0} \setminus \Sigma$ and a 4-valued graph $\Gamma_4 \subset \Gamma$ so Σ^M "passes between" Γ_4. Second, (a slight variation of) Theorem III.2.4 gives the 2-valued graph $\Sigma_d \subset \Sigma$.

Before proceeding, we choose the constants. Let C_3, δ_2 be given by Lemma II.3.8 (with $N = 4$), d_1, d_2 be from Theorem III.2.4, and C_g, β_s be from Lemma I.0.9. Set $\tau_1 = \min\{\tau/(5\, C_g), \beta_s/5, d_2/10\}$ and $\tau_2 = \min\{\delta_2/3, \tau_1/(1 + 3\, C_3)\}$. Let N_1, Ω_1, ϵ be given by Theorem II.0.21 (with τ there equal to τ_2). For convenience, assume that $N_1 \geq 16$ is even, $\Omega_1 > 4$, and rename this ϵ as ϵ_1. Set $N = N_1 + 3$, $\Omega = \max\{d_1, 8\, d_3\, \Omega_1\}$, and

$$\epsilon = \min\left\{\epsilon_1, \epsilon_1/(5\, C_g), \beta_s/5, 1/4, d_2/10\right\}. \tag{IV.0.5}$$

For $N_2 \leq N$ and $r_0 \leq r_2 < r_3 \leq 1$, let $E^{N_2}_{r_2, r_3}$ be the region in $\Pi^{-1}(D_{r_3} \setminus D_{r_2})$ between the sheets of the (concentric) N_2-valued subgraph of Σ_g. Note that $E^{N_2}_{r_2,r_3} \subset \{x_3^2 \leq \epsilon^2\, (x_1^2 + x_2^2)\}$.

As in the proof of Theorem I.0.8, let $\sigma_g \subset \Sigma_g$ be an $(N_1 + 2)$-valued graph over ∂D_{r_0} and let $\gamma_3 \subset \Sigma$ be a curve with six pieces: σ_g, two segments, γ^t, γ^b, in Σ_g which are graphs over a portion of the positive part of the x_1-axis, two nodal curves, σ^t, σ^b, in $\{x_1 = 2\, d_3\, r_0\}$, and $\sigma^\partial \subset \partial\Sigma$. By [MeYa], there is a stable embedded disk $\Gamma \subset B_{R_0} \setminus \Sigma$ with $\partial\Gamma = \gamma_3$.

Let $\{\sigma_i\}$ be the components of $B_{5/8} \cap \{x_1 = 2\, d_3\, r_0\} \cap \Sigma_g$ and suppose that a curve $\sigma \subset \sigma^t$ connects γ^t to a point y_0 between σ_i, σ_{i+1}. By Theorem III.2.4, the portion Σ_{y_0} with $y_0 \in \Sigma_{y_0}$ of $E^{N_1+5/2}_{3\, r_0, 5/8} \cap \Sigma$ is a graph. Note that $B_{d_3\, r_0} \cap \Sigma_{y_0}$ and $B_{3\, r_0} \cap \Sigma_g$ are in the same component of $B_{d_3\, r_0} \cap \Sigma$, since else the stable disk between them given by [MeYa] would intersect Σ_g (using [Sc]). Applying the maximum principle as before gives the desired contradiction. Hence, σ^t, σ^b do not intersect between any of the σ_i's. Therefore, if $z \in E^{N_1+1}_{4d_3\, r_0, 1/2} \cap \Gamma$, then

$$\mathrm{dist}_\Gamma(z, \partial\Gamma) \geq |\Pi(z)|/4\,. \tag{IV.0.6}$$

By the same linking argument as before, $E^{N_1+1}_{4d_3\, r_0, 1/2} \cap \Gamma$ contains an N_1-valued graph Γ_g over $D_{1/2} \setminus D_{4\, d_3\, r_0}$ with gradient $\leq 5\, C_g\, \epsilon$, $\Pi^{-1}(\partial D_{4\, d_3\, r_0}) \cap \Gamma_g \subset \{|x_3| \leq 4\, \epsilon\, d_3\, r_0\}$, and a curve $\eta \subset \Pi^{-1}(D_{4\, d_3\, r_0}) \cap \Gamma \setminus \partial B_{R_0}$ connects Γ_g to $\partial\Gamma \setminus \partial B_{R_0}$. Since $\Omega_1 < 1/(8\, d_3\, r_0)$, Theorem II.0.21 implies that Γ contains a 2-valued graph Γ_d over $D_{R_0/\Omega_1} \setminus D_{4\, d_3\, r_0}$ with gradient $\leq \tau_2 < 1$. In particular, $\Gamma_d \subset \{x_3^2 \leq \tau_2^2 (x_1^2 + x_2^2)\}$. Next, we apply Lemma II.3.8 to extend Γ_d to a 4-valued graph Γ_4 over $D_{5\, R_0/(6\, \Omega_1)} \setminus D_{5\, d_3\, r_0}$ with gradient $\leq \tau_2 + 3\, C_3\, \tau_2 \leq \tau_1$. Let E_Γ be the region in $\Pi^{-1}(D_{R_0/(2\, \Omega_1)} \setminus D_{15\, d_3\, r_0})$ between the sheets of the (concentric) 3-valued subgraph of Γ_4, so that $E_\Gamma \subset \{x_3^2 \leq \tau_1^2\, (x_1^2 + x_2^2)\}$.

If $z \in E_\Gamma \cap \Sigma$, then there is a curve $\gamma_z \subset \Gamma_4$ with each component of $\gamma_z \setminus \Pi^{-1}(D_{5\,d_3\,r_0})$ a graph over the segment $\gamma_{0,z}$, $\partial\gamma_z = \{y_z^2, y_z^4\}$, and y_z^2, y_z^4 are in distinct components of $B_{3\,|\Pi(z)|/5}(\Pi(z)) \cap \Gamma$ with z between these components. By (a slight variation of) Theorem III.2.4 (using $\Sigma \cup \Gamma$ as a barrier rather than just Σ), the portion of Σ inside $B_{R_0/d_1} \cap E_\Gamma$ is a graph over Γ_4. This is nonempty since $(\Sigma_g)^M$ begins in E_Γ, so we get the desired 2-valued graph Σ_d with gradient $\leq 5\,C_g\,\tau_1 \leq \tau$ (by Lemma I.0.9). □

Appendix A. Catenoid foliations

We recall here some consequences of the maximum principle for an embedded minimal surface Σ in a slab. Let $\mathrm{Cat}(y)$ be the vertical catenoid centered at $y = (y_1, y_2, y_3)$ given by

$$\mathrm{Cat}(y) = \{x \in \mathbf{R}^3 \,|\, \cosh^2(x_3 - y_3) = (x_1 - y_1)^2 + (x_2 - y_2)^2\}\,. \tag{A.1}$$

Given $0 < \theta < \pi/2$, let $\partial N_\theta(y)$ be the cone

$$\{x \,|\, (x_3 - y_3)^2 = |x - y|^2 \,\sin^2\theta\}\,. \tag{A.2}$$

Since $\cosh t > t$ for $t \geq 0$, it follows that $\partial N_{\pi/4}(y) \cap \mathrm{Cat}(y) = \emptyset$. Set

$$\theta_0 = \inf\{\theta \,|\, \partial N_\theta(y) \cap \mathrm{Cat}(y) = \emptyset\}\,, \tag{A.3}$$

so that $\partial N_{\theta_0}(y)$ and $\mathrm{Cat}(y)$ intersect tangentially in a pair of circles. Let $\mathrm{Cat}_0(y)$ be the component of $\mathrm{Cat}(y) \setminus \partial N_{\theta_0}(y)$ containing the neck $\{x \,|\, x_3 = y_3, (x_1 - y_1)^2 + (x_2 - y_2)^2 = 1\}$. If $x \in \mathrm{Cat}_0(y)$, then $\overline{y, x} \cap \mathrm{Cat}_0(y) = \{x\}$ since cosh is convex and $\cosh'(0) = 0$; i.e., $\mathrm{Cat}_0(y)$ is a radial graph. Dilating $\mathrm{Cat}_0(y)$ (see fig. 18) gives a minimal foliation of the solid (open) cone

$$N_{\theta_0}(y) = \{x \,|\, (x_3 - y_3)^2 < |x - y|^2 \,\sin^2\theta_0\}\,. \tag{A.4}$$

The leaves have boundary in $\partial N_{\theta_0}(y)$ and are level sets of the function f_y given by

$$y + (x - y)/f_y(x) \in \mathrm{Cat}_0(y)\,. \tag{A.5}$$

Choose $\beta_A > 0$ small so that $\{x \,|\, |x_3 - y_3| \leq 2\,\beta_A\,h\} \setminus B_{h/8}(y) \subset N_{\theta_0}(y)$ and

$$\{x \,|\, f_y(x) = 3\,h/16\} \cap \{x \,|\, |x_3 - y_3| \leq 2\,\beta_A\,h\} \subset B_{7\,h/32}(y)\,. \tag{A.6}$$

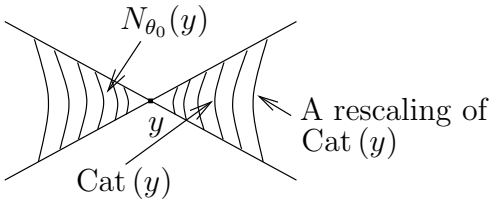

FIGURE 18. The catenoid foliation.

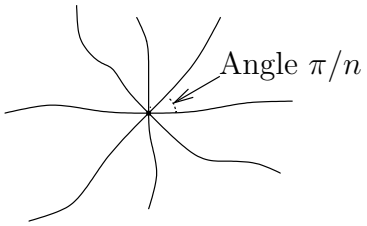

FIGURE 19. An n-prong singularity.

The intersection of two embedded minimal surfaces is locally given by $2n$ embedded arcs meeting at equal angles as in fig. 19, i.e., an "n-prong singularity" (e.g., the set where $(x + iy)^n$ is real); see claim 1 in lemma 4 of [HoMe]. This immediately implies:

Lemma A.7. If $z \in \Sigma \subset N_{\theta_0}(y)$ is a nontrivial interior critical point of $f_y|_\Sigma$, then $\{x \in \Sigma \,|\, f_y(x) = f_y(z)\}$ has an n-prong singularity at z with $n \geq 2$.

As a consequence, we get a version of the usual strong maximum principle:

Lemma A.8. If $\Sigma \subset N_{\theta_0}(y)$, then $f_y|_\Sigma$ has no nontrivial interior local extrema.

Corollary A.9. If $\Sigma \subset B_h(y) \cap \{x \,|\, |x_3 - y_3| \leq 2\,\beta_A\, h\}$, $\partial\Sigma \subset \partial B_h(y)$, and $B_{3\,h/4}(y) \cap \Sigma \neq \emptyset$, then $B_{h/4}(y) \cap \Sigma \neq \emptyset$.

Proof. Scaling (A.6) by 4, $\{x \in \Sigma \,|\, f_y(x) = 3\,h/4\} \subset B_{7\,h/8}(y) \setminus B_{3\,h/4}(y)$. By Lemma A.8, f_y has no interior minima in Σ so the corollary now follows from $f_y(x) \leq |x - y|$. □

Iterating Corollary A.9 along a chain of balls gives:

Corollary A.10. If $\Sigma \subset \{|x_3| \leq 2\,\beta_A\, h\}$, $p, q \in \{x_3 = 0\}$, $T_h(\gamma_{p,q}) \cap \partial\Sigma = \emptyset$, and $y_p \in B_{h/4}(p) \cap \Sigma$, then a curve $\nu \subset T_h(\gamma_{p,q}) \cap \Sigma$ connects y_p to $B_{h/4}(q) \cap \Sigma$.

Proof. Choose $y_0 = p, y_1, y_2, \ldots, y_n = q \in \gamma_{p,q}$ with $|y_{i-1} - y_i| = h/2$ for $i < n$ and $|y_{n-1} - y_n| \leq h/2$. Repeatedly applying Corollary A.9 for $1 \leq i \leq n$, gives $\nu_i : [0,1] \to B_h(y_i) \cap \Sigma$ with $\nu_1(0) = y_p$, $\nu_i(1) \in B_{h/4}(y_i) \cap \Sigma$, and $\nu_{i+1}(0) = \nu_i(1)$. Set $\nu = \cup_{i=1}^n \nu_i$. □

This produces curves which are "h-almost monotone" in the sense that if $y \in \nu$, then $B_{4\,h}(y) \cap \nu$ has only one component which intersects $B_{2\,h}(y)$.

Corollary A.11. If $\Sigma \subset \{|x_3| \leq 2\,\beta_A\, h\}$ and E is an unbounded component of $\mathbf{R}^2 \setminus T_{h/4}(\Pi(\partial\Sigma))$, then $\Pi(\Sigma) \cap E = \emptyset$.

Proof. Given $y \in E$, choose a curve $\gamma : [0,1] \to \mathbf{R}^2 \setminus T_{h/4}(\Pi(\partial\Sigma))$ with $|\gamma(0)| > \sup_{x\in\Sigma} |x| + h$ and $\gamma(1) = y$. Set $\Sigma_t = \{x \in \Sigma \,|\, f_{\gamma(t)}(x) = 3\,h/16\}$. By (A.6), $\Sigma_t \subset B_{7\,h/32}(\gamma(t))$, so that $\Sigma_0 = \emptyset$ and $\Sigma_t \cap \partial\Sigma = \emptyset$. By Lemma A.8, either $\Sigma_t = \emptyset$ or Σ_t contains an arc of transverse intersection. In particular, there cannot be a first $t > 0$ with $\Sigma_t \neq \emptyset$, giving the corollary. □
